THE ETIOLOGY OF LYMPHOBLASTOMA

CHAIRMAN'S ADDRESS

ARTHUR U. DESJARDINS, M.D.
ROCHESTER, MINN.

It may seem presumptuous for a mere radiologist to venture into the field of clinical medicine. The clinician's idea of a radiologist sometimes is that of a queer being who inhabits dark places, sees curious things, and talks a strange language compounded of wavelenghts designated by Greek letters that remind one of college fraternities, of roentgens, and of the relative radiosensitiveness of different varieties of cells. It so happens that, when they undertook to acquire the extra knowledge essential for the sound practice of radiology, some radiologists were perverse enough to retain an interest in clinical medicine. I happen to be one of them. It is perhaps unfortunate that a larger proportion of those who have adopted this specialty have not seen fit to follow this example.

In my own case, the circumstances of life have given me an exceptional opportunity to see and to examine a large number of patients with lymphoblastoma, and, being mildly curious by nature, I have not been able to avoid taking what might be regarded as a morbid interest in this form of physical morbidity. During the past fourteen years, I have been called on to examine and to treat between 500 and 600 patients suffering from Hodgkin's disease or lymphosarcoma, and such an experience, naturally, could hardly fail to give rise to thoughts and queries that would not be likely to arise under different circumstances.

The precise character of the pathologic conditions collectively designated by the term lymphoblastoma still eludes the physician. Although these conditions have been the object of extensive study, pathologists still are far from agreement on the essential and differential characteristics of Hodgkin's disease and lymphosarcoma. Some regard these conditions as essentially malignant and as different phases of the same process, while others insist that Hodgkin's disease is an entity quite distinct from lymphosarcoma. Suffice it to say that, among pathologists, confusion reigns and will probably continue to reign for some time. As far as the leukemias are concerned, divergences of opinion still exist, but these relate mainly to details.

To judge by present-day writings, the etiologic factors responsible for Hodgkin's disease and lymphosarcoma are still as vague and uncertain as they have been for years. At different times in the past the idea

that these conditions might have an infectious basis has been advanced. At one time it was held that these usually fatal disturbances of the lymphoid structures were due to an antecedent tuberculous infection; this idea probably emanated from the observation of undoubted lymphoblastoma occurring in patients who previously had been known to suffer from some tuberculous lesion. Later, other writers attempted to incriminate different micro-organisms which, having been found in lymphoid tissue affected by lymphoblastoma, were regarded as specific etiologic agents. Unfortunately for the protagonists of the etiologic significance of this or that variety of bacteria, their observations or conclusions have not been supported by subsequent investigations, and it now appears established that lymphoblastoma is not invariably due to any one micro-organism.

Extended observation of a large number of cases has led me to note certain features which, from the standpoint of etiology, have struck me as inescapably significant. So much so, indeed, that in my own mind the etiology of lymphoblastoma no longer seems uncertain.

First of all it is essential to consider the immediate cause. On two previous occasions I¹ have intimated that the factor immediately responsible for lymphoblastomatous hyperplasia of the lymphoid structures is chronic infection of any kind. This may be tuberculous, pyogenic or even syphilitic; in fact, the variety of infection is of little consequence, provided the infectious element has been present for a sufficiently long time. The duration of infection may vary considerably in different patients. If the history of the patient's physical ailments is carefully and persistently inquired into, evidence of infection of long standing will be obtained in the majority of cases. However, if the historical inquiry is to yield the desired information it must be pursued with method. In this particular, indeed, it is because of lack of method that so many physicians in the past have failed to elicit clues strongly suggestive of a clear relationship between chronic infection and lymphoblastoma.

For example, after the patient has described the sequence of events connected with his present illness, it is not sufficient to ask the stereotyped question "What other illnesses have you had?" Usually this question would receive an unhesitatingly negative answer. By the average patient such a question is taken to mean what other serious, incapacitating or bed-impelling illness he may have had. While being careful to avoid suggestive or leading interrogations, one should explain to the patient that the medical inquirer is interested not

Read before the Section on Radiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

1. Desjardins, A. U.: Radiotherapy for Hodgkin's Disease and Lymphosarcoma, *J. A. M. A.* 99: 1231-1235 (Oct. 8) 1932; Roentgen Therapy in. Mock, H. E.; Pemberton, Ralph, and Coulter, J. S.: Principles and Practice of Physical Therapy, Hagerstown, Md., W. F. Prior Company, 1932, volume 3, chapter 6, p. 40.

so much in illnesses that may have forced the patient to interrupt his activities and go to bed as in less severe and more prosaic and annoying disturbances. After this explanation, the following questions should be asked: During the past ten years, or at any time in your life, have you had trouble with your teeth? As a child, or since, have you been subject to sore throat or tonsillitis? Have you had any trouble from sinusitis? Have you had repeated earache? Have you had frequent bronchial colds? The interrogation should be continued systematically so as to elicit information concerning the gallbladder and other parts of the gastro-intestinal and genito-urinary tracts. If the questioning is well done and if the wording of the questions is adjusted to the intelligence and social status of the patient, evidence of chronic infection will be obtained in a large proportion of patients.

Still more significant, however, the chronic infection invariably has affected a part of the body drained by the group of lymph nodes that first gave indications of lymphoblastomatous hyperplasia. If information to indicate this is not obtained, the questioning should be resumed, because such inconsistency points to a lapse in the chain of evidence. The practically constant association of infection and primary lymphadenopathy in the same region and on the same side of the body can hardly be regarded as a coincidence. If this were a result of chance, the anatomic relationship would not be so consistent. Quite naturally, one at first is tempted to think that, since so few relatively healthy persons have not had some form of infection at some time during their lives, the assumption that lymphoblastoma depends on infection should be accurate in approximately half of the cases. Actually, the frequency of such relationship in related regions is so much greater than this that the conclusion of an etiologic relationship is inescapable.

But a definite and unquestionable history of chronic infection in a region drained by the nodes first affected with lymphoblastoma cannot always be obtained. Failure in this respect is especially prone to occur in dealing with any of three groups of patients: patients who are farmers or laborers and who, being obliged to work hard and steadily to maintain the family, give little attention to comparatively minor ailments and continue their labors when others would be inclined to seek relief; patients of limited intelligence, and patients whose initial or only manifestations of lymphoblastoma have been confined to the abdomen. Unless fairly pronounced, infection of abdominal structures, such as cholecystitis, ureteritis or pyelonephritis, may not attract the attention of the patient. Chronic gonorrheal or pyogenic infection of the prostate gland or oviducts may lead to secondary lymphadenitis and lymphoblastoma in the retroperitoneal, para-aortic nodes, without the patient being aware of what is going on. Many men may for years have had chronic bronchitis which they have attributed to smoking, and this assumption may have been entirely warranted; but the bronchitis, whatever may have been its cause, may also lead to lymphoblastoma, first in the mediastinal nodes but later spreading to groups of nodes in other parts of the body.

Besides the groups mentioned, a clear history of chronic infection cannot be obtained from a small proportion of other, quite intelligent, patients, probably because the factor of infection has been obscure.

In a small proportion of cases (less than 10 per cent) also more or less clear indications of an antecedent

tuberculous process may be noted, but in the majority of patients tuberculosis does not appear to play an etiologic part.

Chronic infection of any kind, therefore, appears to be the immediate cause of Hodgkin's disease and lymphosarcoma, as it probably is also of the various forms of leukemia. But even if this etiologic relationship is undeniable, a predisposing factor also is required to provide a suitable background for the immediate cause. Otherwise, how could one account for the fact that so many persons may harbor chronic infection for months or years and never suffer from lymphoblastoma? This additional and essential element is probably to be found in a hereditary predisposition or tendency, transmitted from generation to generation, of the lymphoid tissue to react in a certain way to various noxious influences. Since each human being is bound to inherit tissues that, from the cellular, physiologic and pathologic points of view, are a composite of the tissues of his ancestors, it is logical to assume that if, among the patient's immediate or remote progenitors, there has been a tendency to disturbances of the lymphoid system, such a tendency is almost certain to reappear among the descendants. Moreover, evidence to substantiate this assumption is not lacking. As an example, the tendency to adenoid and tonsillar hyperplasia among the children of certain families is well known. Among patients suffering from lymphoblastoma it is not a rare experience to encounter the disease affecting two or more members of a family. Instances of this kind have been reported from time to time and, in my own experience of more than 500 cases, several patients have told me of brothers, sisters or other relatives who had succumbed to the same disease. Within one month I saw a young woman with Hodgkin's disease, who, when I asked why she was so exceptionally concerned about her condition, admitted that only six years before her only brother had died of the same thing.

In order to illustrate the frequency with which the theme of chronic infection appears in cases of Hodgkin's disease and lymphosarcoma, I take the liberty of giving briefly a few reports of cases encountered within a limited period. Were space available, the number of such cases could be increased ad infinitum.

CASE 1.—A man, aged 32, first had noticed enlargement of the left inguinal nodes in July 1933, of the left axillary and right inguinal nodes two weeks later, and of the right cervical nodes still one month later. When the patient was questioned, he revealed that he had contracted syphilis (chancre) three years previously and had had left inguinal adenitis at the time. He also stated that he had had chronic appendicitis (the appendix had been removed in 1927, without relief), and this was followed by "stomach trouble." The first impression was that the rather general lymphadenopathy might be syphilitic. Microscopic examination of sections of a node removed from the neck gave evidence of "chronic inflammation." Roentgen irradiation of all enlarged nodes was followed by such rapid regression that the clinical assumption of syphilitic lymphadenopathy had to be discarded in favor of lymphoblastoma on a syphilitic background.

CASE 2.—A man, aged 47, had noticed enlargement of the right tonsil in 1930. The tonsil had been removed in July 1930, and enlarged cervical lymph nodes on the right side of neck had been removed elsewhere in November 1930. Since 1907 he had had repeated infections of the throat. In February 1933 he had had an attack of severe pain in the midthoracic region; the pain had extended to the left shoulder and had continued for two days. Since then he had been short of breath. In March 1933 the patient had had a second attack of pain around

the left shoulder and left side of the abdomen. He had been unable to take a full meal because of pain in the epigastrium.

On examination, a large, nodular mass was found in the upper part of the abdomen, on the left side. Microscopic examination of sections of a cervical node, previously removed elsewhere, gave evidence of Hodgkin's disease.

CASE 3.—A man, aged 37, had had influenza, with marked nasopharyngeal inflammation, in October 1932. Shortly afterward, the right postauricular nodes had swelled. He had contracted influenza a second time in the spring of 1933. The left postauricular and cervical nodes on both sides had enlarged, and the hyperplastic enlargement had continued. In July 1933 the mediastinal nodes had enlarged. Roentgen irradiation had been followed by typical lymphoblastomatous regression, with rapid but temporary improvement. Since then the disease had been kept under control by occasional irradiation.

CASE 4.—A girl, aged 15 years, had been aware for six weeks of enlarged left cervical nodes, and for three weeks of enlarged right cervical nodes. The lymphadenopathy had continued to increase and, on examination, the mediastinal and retroperitoneal nodes also were found to be enlarged. Biopsy gave evidence of Hodgkin's disease. Further inquiry into the patient's physical antecedents revealed that, between the ages of 4 and 9 years, she had had repeated attacks of tonsillitis. The tonsils had not been removed.

CASE 5.—A man, aged 40, three months before he came to the clinic first had become aware of an enlarged left axillary node, the diameter of which had increased to about 9 cm. Microscopic examination of the excised mass of left axillary nodes gave evidence of lymphosarcoma. Shortly thereafter the left axillary, then the right axillary and inguinal, nodes also became enlarged. Although the patient himself was not conscious of abdominal lymphadenopathy, he complained that for some time he had been distressed by increasing constipation, which had disappeared after roentgen irradiation of the abdomen. The enlarged nodes in other regions also had retrogressed. On further inquiry it was found that for some years the patient had suffered from dental sepsis and from biliary disturbances, which had been regarded as manifestations of cholecystitis. In this case the sequence of events and the low grade of intelligence of the patient made it impossible to determine clearly whether the lymphoblastoma had originated in the cervical or in the abdominal nodes. Chronic infection had been present in both regions.

CASE 6.—A woman, aged 44, had become aware, about July 1933, of general pruritus, and lymph nodes on the left side of neck had become enlarged. Apparently thinking that these symptoms were related to the menopause, a physician had prescribed ovarian extract for two months. The face and neck rapidly had become puffy, and dyspnea had developed. Later the skin and subcutaneous tissues over the left breast and anterior aspect of the thorax had become infiltrated. Examination disclosed marked bilateral enlargement of the cervical lymph nodes, with engorgement of the superficial veins of the face and neck; moderate enlargement of the axillary nodes on both sides; mediastinal lymphadenopathy with moderate, bilateral hydrothorax; marked cutaneous and subcutaneous infiltration of the left breast and anterior part of the thorax, with distended and tortuous veins; and enlarged retroperitoneal nodes, with general pruritus (excoriations from scratching).

Inquiry revealed that the woman had had extensive dental infection for some time prior to the onset of her illness and that seven teeth had been extracted on this account in May 1933. The remainder of the infected teeth were to be extracted later.

CASE 7.—A woman, aged 56, for at least two years had been aware of enlarged submaxillary and cervical nodes and later of enlarged axillary and inguinal nodes. The lymphadenopathy had begun on the left side of the neck. The mediastinal and other regions were found free from enlarged nodes, as far as could be determined. The left tonsil was abnormally large, extended almost to the median line of the pharynx, and had been large for a long time. Some of the lower teeth on the left side harbored chronic infection.

CASE 8.—A girl, aged 8 years, during the winter of 1932-1933 had had three attacks of tonsillitis, and two additional bouts

of tonsillar infection had occurred in September and October 1933. The last attack had continued for about two weeks. Instead of returning to normal size, as did the tonsil on the left side, the right tonsil had continued to enlarge. A biopsy in January 1934 disclosed severe inflammation akin to that which accompanies Vincent's infection. By this time the lymphoid hyperplasia had extended to the right cervical nodes, which, in the upper part of the neck on the right side, now formed a mass measuring 5 by 3 cm. The right tonsil had been removed elsewhere, but in spite of this the right cervical lymphadenopathy steadily had increased until in April 1934 a mass measuring approximately 15 by 10 cm. had been found. Under treatment by roentgen rays the size of the mass diminished 50 per cent in four days and completely disappeared during the ensuing two weeks. The child's general condition improved correspondingly. Then she began to complain of abdominal discomfort and her respiration became visibly embarrassed. Both the abdominal pain and dyspnea increased rapidly and, when she was examined one week later, a large, firm mass could be palpated in the lower part of the abdomen; besides this, roentgenographic examination revealed mediastinal lymphadenopathy. It is evident that the disease is extending rapidly, as it so often does in children.

CASE 9.—Late in December 1932 or early in January 1933 a woman, aged 37, had become conscious of pain around the right hip, and the pain had extended down the right thigh and leg. She also had had a sense of pressure in the back (lumbar region) and around the rectum. The pain around the right hip had been accompanied by urticaria. A gynecologist whom she had consulted had inserted a pessary, which she still wore when she came to the clinic but from which she did not derive any relief. Another physician had injected varicose veins at the anterior part of the right thigh, also without relief. During the latter part of January 1933 a third physician had found a mass in the epigastrium, and exploratory laparotomy had been advised. At operation (elsewhere) a mass infiltrating the upper part of the mesentery, and inoperable, had been found; microscopic examination of sections from this mass gave evidence of lymphosarcoma.

Review of the woman's medical antecedents disclosed that in 1925 and 1926 she had had repeated attacks of right ureterolithiasis and had continued to suffer from this afterward. At one time during this period she had been in bed for three months. Repeatedly she had been subjected to cystoscopic examination. In September 1926 a stone had been removed surgically from the right ureter. In 1927 a diagnosis of right pyelonephritis had been made by an eminent urologist.

CASE 10.—In 1922 a woman, aged 57, had had repeated attacks of severe, colicky pain (which she described as "worse than labor pains") in the upper right quadrant of the abdomen. The pain had extended across the abdomen and through to the back. These attacks had recurred about every ten days for two or three months and had not been accompanied by jaundice. The most severe attack had lasted about an hour but, on the average, the other attacks had not extended much beyond thirty minutes. When these attacks had subsided, soreness and tenderness of the anterior abdominal wall had persisted for some time. In the ensuing two years she had had only mild attacks, lasting from fifteen to twenty minutes. The painful seizures had been associated with gaseous distention and bloating. In 1924 she had had a series of similar attacks for a period of about three months. After this the abdominal disturbance had smoldered until February 1933, when pain in the upper left abdominal quadrant, associated with an almost continuous pain in the epigastric region, had developed. Also the patient had recently become conscious of a large, firm mass in the upper left abdominal quadrant.

Palpation of the abdomen disclosed a hard, movable mass occupying the epigastric and left hypochondriac regions. In June 1933 an exploratory laparotomy was performed; the surgeon found a neoplasm involving the entire posterior wall and greater curvature of the stomach, with numerous enlarged retroperitoneal lymph nodes extending along the lesser curvature, upward to the esophagus. Microscopic examination of a piece of tissue from the wall of the stomach gave evidence of lymphosarcoma.

CASE 11.—A woman, aged 66, had noticed in November 1932 a slightly enlarged node on the right side of the neck. In January 1933 she had had a severe infection of the respiratory tract, with much cough and expectoration of mucopurulent material and had continued to cough since that time. Since the end of 1932 also the lymph nodes in the neck, especially on the right side, had progressively enlarged. A biopsy on a node from the right side of the neck gave evidence of Hodgkin's disease. Questioning brought forth the information that, for many years, the patient had suffered from pyorrhea, and twenty-seven teeth had been extracted for this reason in the summer of 1932.

CASE 12.—In the early fall of 1932 a man, aged 42, had begun to suffer from "heartburn" and gastro-intestinal distress, which had come on one or two hours after meals. The symptoms gradually had increased, his weight had unaccountably begun to diminish, and these gastro-intestinal disturbances had been accompanied by belching and increasing constipation. In March 1933 the patient had been ill with influenzal pneumonia for three weeks; during this period he had had a high fever and, even after the infection had subsided, he had not fully recovered his health. Between the onset of his first symptoms in the fall of 1932 and his registration at the Mayo Clinic in July 1933 his weight had diminished from 230 to 167 pounds (from 104 to 76 Kg.). During the month preceding his examination, dyspnea had developed and he had passed tarry stools. Examination disclosed a large, irregular mass in the upper left quadrant of the abdomen, and bilateral enlargement of the mediastinal lymph nodes. Under roentgen irradiation the markedly enlarged abdominal and mediastinal nodes rapidly diminished in size, and all the patient's symptoms abated as promptly. Further investigation disclosed that the patient had suffered from marked pyorrhea for years.

In this case it seems likely that, by feeding infectious material to the gastro-intestinal tract over a long period, the pyorrhea probably had initiated the lymphoblastomatous process in the abdominal nodes, and later it had extended upward to the mediastinal nodes.

If chronic infection as the immediate cause of lymphoblastoma is as significant as it appears to be, it behooves the physician actively to combat infection wherever it may appear and, by every means in his power, to prevent such infection from becoming endemic, so to speak. Patients should not be allowed to harbor indefinitely teeth, tonsils, a gallbladder or other structures that are known to be infected. The importance of this conclusion is all the greater when the ancestors of the patient have been known to suffer from lymphoid disturbances. But, since few patients possess definite and reliable knowledge about the cause of death of even their parents and relatives of the first degree, certainly their knowledge of the morbid tendencies of distant relatives must be even more limited and less dependable. Under these circumstances the duty of the physician is plain.

The Deficiency Diseases.—One of the most notable contributions that has been made to medicine during the last quarter of a century is the discovery of the accessory food factors, the vitamins. With a comprehension of the significance of the vitamins has come an increasing interest in the subject of malnutrition in its broadest sense. As a result of innumerable investigations the tendency has grown within recent years to gather into one group a number of disease states that have been defined somewhat loosely as the deficiency diseases. The deficiency which is common to all of them is an inadequate amount of some substance in the food which is necessary to the body for its proper nutrition, or the inability of the body to absorb, or to prepare for absorption, these necessary substances even though the diet contains sufficient quantities of them.—Longcope, W. T.: The Importance of Disturbances in Nutrition in Edematous States, *New England J. Med.* **210**:1243 (June 14) 1934.

PULSATING EXOPHTHALMOS DUE TO INTERNAL CAROTID-JUGULAR ANEURYSM

THE USE OF THORIUM DIOXIDE SOL
IN LOCALIZATION

T. L. TERRY, M.D.

AND

PHILIP MYSEL, M.D.

BOSTON

Pulsating exophthalmos is usually the result of an abnormal arteriovenous communication in or just behind the orbit.¹ The pressure in the vein or in the venous sinus is raised so that it approaches the pressure in the artery. As a result, all anastomoses of these vessels and their capillary beds are greatly altered. Reid² states that abnormal arteriovenous communications give the greatest stimulus to establishment of collateral circulation. There is an actual increase in the number of capillaries, and all anastomoses to surrounding channels are increased in size. The veins are distended into varicosities (fig. 1).

This, of course, holds true especially in the orbit, since the orbital veins connect with both the external and the internal jugular vein. The increase in volume of the orbital content is produced by the increased volume of blood in the vascular bed and by the edema resulting from the distention of vessels. Arterial pulsation is also carried over into the veins and is transmitted to the eye. Pulsation of the eye is not always obvious and it is sometimes necessary to apply pressure to the globe in order to elicit the pulsation.³

Usually the paired venous sinuses of the skull communicate freely with one another and with tributaries to the external jugular veins. The important communications are between the cavernous sinuses by means of the anterior and the posterior intercavernous sinuses; between the straight sinus, usually on the left, and the transverse sinus, usually on the right, by the "confluens sinuum"; between the jugular bulbs by the occipital sinuses, and between the intracranial sinuses and the tributaries of the external jugular vein by emissary veins, by the pterygoid plexus, and indirectly by the angular vein (fig. 2). Thus the increased venous pressure caused by an arteriovenous aneurysm between the internal carotid artery and the internal jugular vein should be well distributed to all the venous sinuses of the skull, through them to the opposite internal jugular vein and to both external jugulars.⁴

With such a widespread distribution of the back pressure one would not usually expect to find enough effect on the cavernous sinus of the same side to produce a pulsating exophthalmos. The superior sagittal sinus usually terminates by emptying into the right transverse sinus, but it may empty into the left trans-

verse sinus or it may even bifurcate and empty into both transverse sinuses. Edwards⁵ has found marked variations in the outgoing venous sinuses of the skull. De Schweinitz and Holloway¹ found that pulsating exophthalmos became bilateral in seven of the sixty-nine cases they analyzed. They say: "Following the venous distention on one side, there is an extension of the process by the transverse and the circular sinus to the venous channels of the opposite side. There is not a simultaneous development of pulsating exophthalmos in the two eyes." An unusually wide communication between the paired sinuses is a logical explanation for these cases that become bilateral.

So far as we can ascertain, the following is the only reported case of pulsating exophthalmos due to an arteriovenous aneurysm in the neck:

REPORT OF CASE

History.—A man, aged 38, awakened at 3 a. m. with a sharp pain in the right temporal region. Ten grains (0.65 Gm.) of acetylsalicylic acid gave no relief. The patient continued his work as a hod carrier for some three days, when the discomfort became so unbearable that he sought relief from his physician. Local applications of heat and some pills were given him. The patient was relieved by the treatment sufficiently to resume his work. However, about three weeks later he noticed a "swishing" sound in his right ear, which was regular but which became more rapid with increased activity. He became dizzy after exertion. He also noted some vertical diplopia, which soon disappeared. The dizziness and the murmur became so intense that the patient could not work. He came to the eye clinic of the Massachusetts Eye and Ear Infirmary four weeks after the onset of his symptoms.

The patient was hit on the vertex of the head with an ax about twenty years previously. Several stitches had to be taken to close the wound. The injury did not render the patient unconscious and he had an uneventful recovery. The patient reported to us that he was hit on the right temporal region by a piece of falling timber about two months before. He considered this accident just a "scratch" and of no significance.

Examination.—There was a small but definite exophthalmos of the right eye. The difference in prominence of the two eyes was 4 mm. as measured by the Hertel exophthalmometer. Careful inspection showed a pulsation of the eye. The pulsation was approximately synchronous with the radial pulse. The superficial veins on the right side of the neck were prominent.

A loud murmur of a shrill musical type, seemingly continuous but greatly accentuated during systole, was heard over the right eye, in the right temporal region and over the internal carotid artery in the neck. It was loudest in the upper part of the neck. A compression of the carotid artery low in the neck immediately stopped the murmur but had no visible effect on the exophthalmos.

Diplopia was not present. The vision in each eye was 20/20. There was 1.5 prism diopters of right hyperphoria. The visual fields and blind spots were normal.

The conjunctival vessels of the right eye were increased in size and were very tortuous. This was particularly evident temporally. In the right fundus the retinal veins were moderately dilated and somewhat more tortuous than usual, though the departure from normal was not striking. The retinal arteries appeared normal in size and distribution. There were no retinal hemorrhages and no signs of retinal edema. The left fundus was quite normal. The pupillary responses were normal in both eyes.

X-ray films of the skull showed no increased density in the orbit. Both optic canals were normal in size and shape. There was no evidence of fracture.

The Wassermann reaction was negative. Neurologic and medical examinations at the Massachusetts General Hospital were essentially negative.

The facts that the exophthalmos was of such a small amount that the murmur was heard loudest in the neck and, that the

superficial cervical veins were prominent were opposed to the assumption that the aneurysm was located in or just behind the orbit. It was thought best to determine, if possible, the location of the aneurysm in order to devise the best method of surgical approach.

The internal carotid artery was cut down on and 25 cc. of thorium dioxide sol was injected into the artery. A series of x-ray films was taken at intervals during and after injections. They showed a somewhat triangular shadow with its base approximately at the site of the injection. The base was wide enough to represent the total width of the internal carotid artery and the internal jugular vein. The apex of the triangle was just below the jugular bulb (fig. 3). None of the thorium entered the skull. There had been very little leakage of the thorium into the soft tissues of the neck. This was shown by an x-ray film taken after sufficient time had elapsed for the thorium in the vessels to be carried off and diluted by the circulation (fig. 4). This roentgenographic evidence was proof that an abnormal arteriovenous fistula existed between the internal carotid artery and the internal jugular vein in the upper part of the neck.

Fig. 1.—Schematic representation of the circulatory changes in arteriovenous aneurysms: A, a simple vascular bed of artery, vein and capillaries. B, effect of the aneurysm in a simple vascular bed, with decrease in size and thickness of the wall of the artery peripheral to the aneurysm, thickened wall and dilatation of the vein both peripherally and centrally, and increase in size and in number of the capillaries. C, normal vascular bed with anastomoses of arteries, veins and capillaries with vessels of neighboring vascular beds. D, aneurysm in the vascular bed; the changes mentioned in B are present and in addition the anastomoses to neighboring vascular beds take part in the pathologic changes; in other words, the collateral circulation has been greatly increased.

Operation (described by Dr. Myself).—Ten days after the thorium dioxide sol had been injected, the patient was taken to the operating room and the wound was reopened under general anesthesia. The internal jugular vein was dissected free and on picking up the vein with forceps one could see whirlpools and eddies of arterial blood within the vein. The jugular and lingual veins were ligated between two ligatures, the common facial vein having been ligated at the time of the injection of the thorium.

The region of the bifurcation and the internal carotid artery for $1\frac{1}{4}$ inches above the bifurcation were found to be infiltrated and boggy, evidently because of the injection of the thorium. For this reason, and also to prevent the back "swish" from the external carotid, the common carotid was ligated first. The incision was then carried farther up the neck and the internal carotid artery was exposed well above the part infiltrated by the thorium and was ligated at this point.

5. Edwards, E. A.: Anatomic Variations of the Cranial Venous Sinuses, Arch. Neurol. & Psychiat. 26: 801 (Oct.) 1931.

The following day the pulsation of the eyeball, the constant tinnitus, the temporal headache, and the bruit over the eyeball and neck had disappeared.

The patient remained in the throat service for two weeks following the carotid and jugular ligations. During this period he complained of slight vertigo only in the morning, when getting out of bed; otherwise his convalescence was uneventful, no cerebral complication developing.

Postoperative Course.—Two days after the operation the intern in the throat service found the right fundus to be pale. Seventeen days after operation the fundus showed a marked pallor but the retinal veins were markedly distended. There was no cherry red spot in the macula. The pallor of the retina was considered to be due to edema. Near the macula were several small somewhat irregular whitish spots, which were considered to be exudate. The vision was reduced to fingers at 4 feet. The confrontation fields were normal. The dizziness on exertion had diminished. Twenty-one days after the operation no changes were observed in the eye. Forty-nine days

Fig. 2.—Composite drawing made by aid of illustrations in Cunningham's Textbook of Anatomy and Spalteholz's Human Anatomy. This shows the venous sinuses of the skull and their usual communications. 1, jugular bulb; 2, transverse sinus; 3, superior sagittal sinus; 4, confluent sinus; 5, cavernous sinus; 6 and 7, anterior and posterior intercavernous sinuses; 8 and 9, superior and inferior petrosal sinuses; 10, ophthalmic vein; 11, occipital sinus. No attempt has been made to show the connections between the tributaries of the internal and external jugular veins. A very important connection is between the ophthalmic vein and the angular vein. The latter, though it is a tributary to the internal jugular vein, has a large connection with the external jugular vein. Very small or absent connections between the paired venous sinuses of the skull at 6 and 7 and at 4 could easily account for a pulsating exophthalmos as a result of an arteriovenous aneurysm between the internal carotid artery and the internal jugular vein.

after the operation the retinal pallor had almost completely disappeared. The vision had improved to 20/70. Five months after the operation the dizziness on exertion had entirely disappeared. The vision was still 20/70. The retinal pallor and the whitish spots had entirely disappeared. There was an irregular indistinct dark spot in the fovea. The venous distention in the retina had disappeared. The exophthalmos was still present.

In 1930 Radt⁶ developed a technic of intravenous injection of thorium dioxide sol to visualize the spleen

and liver. From 10 to 15 cc. of the drug is injected daily until the total dose of from 50 to 75 cc. has been given. In about four days the drug is taken up by the reticulo-endothelial system so that the liver and the spleen are visible as very dense organs in x-ray films. This drug is considered to be dangerous. It is toxic in large doses. It may possibly be radioactive. It is held in the reticulo-endothelial system for years. The Council on Pharmacy and Chemistry of the American Medical Association refused to approve it in 1932.⁷ The report of the council lists the dangers of the drug and raises objections to the use of the term thorotrast (Hayden).

Allen and Camp⁸ had used thorium dioxide sol to visualize arteries in the extremities. They found that a dose of 25 cc. was sufficient. This is not enough to give an x-ray shadow of the liver and spleen. Certainly such small doses should be of much less danger. Moniz⁹ has used thorium dioxide sol to demonstrate the cerebral vessels. The drug has been used by many others for various purposes.

In 1920 Callander¹⁰ collected nine cases of arteriovenous aneurysms between the internal jugular vein and the internal carotid artery. However, Winslow,¹¹ in a more recent review, collected 106 cases of extracranial aneurysms of the internal carotid artery. Of this number nineteen were of the arteriovenous type. Since Winslow's communication I have found in the literature three additional cases of fistula between the internal carotid and the jugular.¹² There is one case of arteriovenous aneurysm between the internal carotid artery and the jugular bulb.¹³ There are five cases¹⁴ of abnormal arteriovenous communication between the common carotid artery and the internal jugular vein. With the exception of the case of Worms and Germain,¹² in which there was a nonpulsating exophthalmos, none of these cases showed any ocular changes.

By far the most interesting paper on arteriovenous aneurysms is by Reid.² He found that the abnormal communications were congenital in six cases out of thirty-three. Reid considers cirroid aneurysms and simple angiomas to be congenital abnormal arteriovenous communications.

Smith¹³ discusses the embryologic basis for congenital arteriovenous aneurysms. In the embryo certain vessels may be arteries for a time and later become veins, and vice versa. He quotes Sabin as stating that the circulatory systems of pig embryos of from 14 to 15 mm. length may still show slender connections

between the middle segment of the internal jugular vein and the internal carotid artery.

Certainly no congenital basis is needed to explain the occurrence of an aneurysm following a perforating wound of an artery and a vein as a result of injury by a sharp cutting instrument, by gunshot wounds, or by spicules or sharp edges of a fractured bone. In those cases, on the other hand, that result from trauma in the nature of a contusion, most assuredly the presence of a diseased vessel wall would play a very important part in the formation of the aneurysm. This may explain to a great extent why aneurysms arise in only a few of the people who sustain practically identical contusions. Reid² reported cases in which trauma to a cirroid aneurysm or even to an angioma produced enlargement and pulsation of the lesion.

COMMENT

It is impossible to be sure that the patient herein discussed did not have more than one arteriovenous communication. Such another fistula intracranially placed would produce the signs and symptoms and would have been cured probably by the same operative procedure. However, it is possible to explain all the conditions on the basis of one lesion.

It is difficult to surmise that an arteriovenous communication of the internal carotid artery and the internal jugular vein could produce pulsating exophthalmos unless there was a very poor or a completely absent communication between the paired sinuses. Edwards⁵ has shown that many types of variations do occur in the venous sinuses of the skull. Probably a faulty communication between the paired sinuses could have been demonstrated in the present case by further injection of thorium dioxide sol on the left side, but the possible remote dangers arising from the accumula-

the arteriovenous aneurysm in this patient. It seems that this aneurysm was spontaneous and most probably of congenital origin.

Reid² points out that there are marked changes in the peripheral parts when an abnormal arteriovenous communication is eliminated. The temperature of the

Fig. 4—Appearance a considerable time after the injection of thorium dioxide sol. The shadow in the neck shows the small amount of thorium dioxide sol that leaked into the soft tissues at the time of the injection.

part is elevated from 1 to 2 degrees. This is due to sudden changes of the circulatory condition. Some time must elapse before a normal equilibrium is reestablished.

Tying the carotid artery is a dangerous operation. If the patient does not die, there is the possibility of hemiplegia.¹⁵ The danger is no doubt lessened by the fact that the aneurysm has increased the collateral circulation. Unless hemorrhage or cardiac symptoms make an early operation advisable, Reid² feels that it is preferable to wait six months before operating on the usual abnormal arteriovenous communication so that the collateral circulation may be fully established. However, in the case of pulsating exophthalmos he feels that an early operation is preferred because the vision may be endangered by increased protusion of the eye.

Tying the internal jugular vein also occasions some disturbance to the eye. It may produce papilledema, distention of the retinal veins, edema of the retina, and even retinal hemorrhages. Reid² feels that it is advisable to tie the accompanying vein when the artery is tied in cases of arteriovenous fistula. Failure to tie the vein leaves the region with an abnormally large venous drainage. Walcker¹⁶ as well as other authors stresses the desirability of ligating the internal jugular vein whenever the carotid artery is tied.

In an attempt to understand the changes in the eye following the operation, several factors must be considered: Ligation of the carotid artery would tend to produce an anemia of the retina, ligation of the internal

tion of thorium in the system makes one hesitate to use such measures when no value to the patient would result.

It is highly improbable that the severe injury to the head twenty years previously or the more recent slight head injury or the combination of the two produced

15. Sahnger, Samuel, and Pearlman, S. J. Hemorrhage from Pharyngeal and Peritonsillar Abscesses, *Arch. Otolaryng.* 15: 464 (Oct) 1933.
16. Walcker, F. *Arch. f. Klin. Chir.* 130: 736, 1924 (quoted by Sahnger and Pearlman¹⁵).

jugular vein would tend to produce a passive congestion of the retina, and elimination of the aneurysm would tend to improve the circulation. A combination of these factors in their indeterminable proportions did produce an edema of the retina and a distention of the retinal veins. The cause of the irregular indistinct dark spot in the fovea is not clear. It might be due to a small choroidal hemorrhage, to proliferation of pigment epithelium of the retina or to the processes of repair following a small flat separation of the retina at this location. Though embolism of choroidal vessels is not generally recognized, it is possible that the operative trauma to the neck vessels might have freed a minute thrombus.

De Schweinitz and Holloway¹ state that "tumors of the brain which have broken into the orbit, as well as tumors of the orbit itself, or protruding into it from the neighboring sinuses, can cause symptoms which are analogous to those furnished by the typical pulsating exophthalmos." The differentiation is usually easily made by roentgenographic means and by the presence or absence of a murmur. However, there are other additional methods of differentiation. Brown¹⁷ calls attention to Branham's sign¹⁸ and to determination of the oxygen content of the venous blood. To determine the oxygen content of the venous blood Brown collects two samples, one from the vein near the fistula and the other from a vein somewhere else in the body. The samples have to be collected under oil. The Van Slyke gasometric method of analysis is done.

The question may arise as to whether the duration of an arteriovenous fistula can be determined. In a case of pulsating exophthalmos in my own practice this question arose, from a medicolegal point of view. Strong evidence for a long duration is furnished by the extent to which the heart has hypertrophied. The heart hypertrophies after a time; the effect on the heart has been compared to that of aortic regurgitation.

CONCLUSIONS

1. An abnormal arteriovenous communication between the internal carotid artery and the internal jugular vein rarely affects the eye.
2. Such an aneurysm produced pulsating exophthalmos in the case herein reported.
3. The exophthalmos probably was due to insufficient communication between the paired cranial sinuses.
4. Thorium dioxide sol is of aid in locating the site of arteriovenous aneurysm.

128 Newbury Street.

ABSTRACT OF DISCUSSION

DR. ADOLPH O. PFINGST, Louisville, Ky.: More than 600 cases have been reported since the condition was first described by Benjamin Travers in 1809. Travers was of the impression that his case was one of cirroid aneurysm of the orbit. He was the first to ligate the common carotid artery for its relief. Autopsy established that many of the cases of pulsating exophthalmos are not of orbital but of intracranial origin and that most of them are brought about by arteriovenous communication. In 1907 de Schweinitz and Holloway, in their classic treatise on pulsating exophthalmos, pointed out that the majority of cases are due to communication between the internal carotid artery and the cavernous sinus. This is especially true of the traumatic cases, which represent about 77 per cent of all arteriovenous aneurysms. Of the spontaneous type of pulsating

exophthalmos, only a little more than half the cases can be attributed to arteriovenous communication, the cause of the other half being about equally divided between orbital tumors and simple aneurysm, either of the internal carotid or of the ophthalmic artery. The author has stated that quite a few cases of exophthalmos have their cause in extracranial arteriovenous communication and that most of them due to fistulous communication between the internal carotid and the internal jugular in the neck are not associated with exophthalmos. His case represents the only one ever reported in which internal carotid-jugular aneurysm was associated with a pulsating exophthalmos. In the intracranial arteriovenous variety of aneurysm the pulsation of the eye can readily be explained by the fact that the anastomosis of the artery and vein brings about a rise of pressure in the vein and thus carries the arterial pulse to the vein of the eye. The increased volume of the orbital contents, the result of increase in blood throughout the orbital vessels, and the edema resulting from the distended vessels are also a potent factor in the transmission of the pulse beat to the eyeball. The interpretation of the cause of the pulse beat in their case by Drs. Terry and Myself, that it was probably due to a poor communication between the paired cranial sinuses and a consequent disturbed collateral flow of blood, seems a theory worthy of consideration when one subscribes to the view that the rare cases of bilateral pulsating exophthalmos are due to a wide communication between the paired sinuses. The mechanism of the production of arteriovenous communications has not been satisfactorily explained.

DR. MONT R. REID, Cincinnati: The problem of dealing with intracranial or subcranial arteriovenous communications is complicated by the dangerous procedure of ligating a large artery proximal to the point or points of communication. The procedure is attended by much more serious complications than the ligation of an artery for arterial aneurysm. Ligations in the cases of intracranial arteriovenous communications lead to a high incidence of cerebral complications. To obviate the dangers of proximal ligation of an artery for pulsating exophthalmos, various methods have been tried. As pointed out by the author, the ligation of a vein to prevent too rapid shunting of blood back to the heart has been advocated. Brooks advocated opening the internal carotid artery and inserting an embolus of muscle, which would go up and block the fistula. De Schweinitz and others have cured many cases by ligating the large supra-orbital vein. Recently a small instrument has been developed consisting of a brush on a flexible probe, which can be inserted back toward the fistula, after division of the supra-orbital vein, in order to traumatize the intima of the vein. The cures reported by ligation of the supra-orbital vein have undoubtedly been due to a retrograde thrombosis. As pointed out by Dr. Terry, pulsating exophthalmos may result from abnormal extracranial arteriovenous communications. His case seems certainly to be of this type. It is most interesting that the condition apparently developed in his patient without any definite injury. One wonders whether the condition was not congenital or at least preceded by a long-standing deep angioma, which, as the result of some stress or strain, developed the characteristics of a cirroid aneurysm exhibiting a thrill and bruit. The occurrence of just one spontaneous communication between large arteries is extremely rare, except in the case of thoracic aneurysms, which may rupture into the vena cava. If his case developed on the basis of an angioma or cirroid aneurysm or is congenital, the chances are that the ligation of the carotid artery will serve only to ameliorate the condition and that the symptoms will recur. This was true in the case in which Halsted operated on a girl 11 years of age for an extracranial cirroid aneurysm situated apparently in about the same position as in the case of Dr. Terry's patient. He ligated the external carotid artery and excised one rather large fistula. Seven years later she had the same symptoms associated with slight exophthalmos, bruit and thrill. At that time I excised a fistula and a very large ascending pharyngeal artery. This relieved the patient for a considerable period but then the bruit and thrill returned.

DR. T. L. TERRY, Boston: Though the case here reported was apparently cured of the pulsating exophthalmos, macular vision in the involved eye was lost. It might have been

17. Brown, G. E.: Abnormal Arteriovenous Communications Diagnosed from the Oxygen Content of the Blood of Regional Veins, *Arch. Surg.* 18: 807 (March) 1929.

18. Branham's sign is the sharp slowing of the pulse with closure of the fistula.

possible to cure the aneurysm without loss of central vision if some other type of operation had been done. The operation as described was apparently the best substitute of operative means available when it was found impossible to perform a so-called quadrilateral ligature with removal of the arteriovenous fistula. Ligation of the veins as suggested by Dr. Reid might have been a more successful procedure. In a paper read last Monday before the Association for Research in Ophthalmology by Dr. George M. Dorrance it was shown that operative obstruction of the common carotid artery would reduce the circulation through the internal carotid artery by 50 per cent. Ligation of the superior thyroid artery along with the common carotid would reduce the flow in the internal carotid by 75 per cent. This operative procedure Dr. Dorrance finds is not nearly so apt to produce cerebral complications. The operation as suggested by Dr. Dorrance might also have cured the aneurysm in the case I have reported without destroying macular vision. Since meningocele extending into the orbit and angioma of the orbit can produce pulsating exophthalmos, it is important to use thorium dioxide and gasometric determination of the oxygen content of the blood from the internal jugular vein to prove conclusively that the pulsating exophthalmos is due to an arteriovenous fistula. However, the presence or absence of a murmur in the involved region would be of great importance in this differentiation.

FORENSIC APPLICATION OF SEROLOGIC INDIVIDUALITY TESTS

KARL LANDSTEINER, M.D.
NEW YORK

Serologic methods were applied in forensic medicine shortly after the discovery of immunologic species characteristics. The specific precipitin reaction made it possible to differentiate human from animal blood even in minute stains, a task beyond the reach of ordinary chemical methods. To go still further and attempt to distinguish bloods of various human individuals from one another seemed almost hopeless at that time. In part this problem was solved by the observation that there exist several types of human blood which can be identified by a very simple reaction, normal human serums being used as reagents.

I presume that the properties of the human blood groups are known well enough to make a repetition unnecessary. Because of the regularity of the blood group scheme it was obvious from the outset that the underlying blood properties are constitutional and, following the rediscovery of Mendel's laws by de Vries, Correns and Tschermak, these individual blood properties were shown to be hereditary and subject to the mendelian rules.¹ Accordingly, the blood group reactions can be resorted to forensically in cases of disputed parentage. I propose to discuss first this application of the blood group tests, which is more common than the differentiation of human blood stains.

Two major theories on the inheritance of the blood groups have been put forward. Since the theory of von Dungern and Hirschfeld, which seemed satisfactory at the outset, has been disproved, it will suffice to present the theory of Bernstein, now generally accepted. One should emphasize, however, that there was never any controversy about the facts most essential for the practical application of the tests and furthermore that with regard to these facts both theories are in agreement.

The theory of Bernstein assumes three allelomorphous genes, A, B and O (or R), one of which is present in each member of a certain pair of chromosomes, genes A and B being dominant over O. Since each somatic cell possesses two of these genes, one derived from either parent, there are six possible genotypes, whose correlation with the four blood groups is given in table 1. The mode of inheritance may be illustrated

TABLE 1.—Correlation of Genotypes with Blood Groups

Genotype	Group (Phenotype)
OO	O
AA } AO }	A
BB } BO }	B
AB	AB

by an example of a mating. Assuming one parent of the genotype AO and the other of the genotype BO, the germ cells of the former contain either the gene A or O and likewise the germ cells of the latter either B or O. Thus there result four possible genotypes in the offspring; namely, AB, AO, OB, OO. In this case, therefore, children of all four groups are possible.

In a like manner the offspring arising from any sort of mating can be derived (table 2). It is evident that the tests cannot be used to prove parentage; on the other hand, an exclusion of paternity can be made not infrequently. These cases fall under two headings. First, the dominant agglutinogens A and B cannot appear in the offspring unless they are present in one or both parents (table 2, lines 1-6); secondly, a parent O cannot have a child AB, and a parent AB cannot have a child of group O (table 2, lines 7-10). The first rule (dominance rule), is common to the two theories mentioned, whereas the second is peculiar to Bernstein's theory.

From the foregoing it follows that a decision as to nonpaternity can be made only in a certain percentage

TABLE 2.—Derivation of Offspring

of cases, since children of the same group can result from matings with men of different groups, and at any rate the falsely accused man and the true father may belong to the same group. The average chance of excluding paternity is about 1/7,² as can be calculated on the basis of the theory of inheritance from the frequencies of the four groups in the population. A point of practical interest is that the chances vary for men of different groups; the figures, as calculated by Hooker and Boyd, are, for group O, one in five; for group A, one in seventeen; for group B, one in seven; for group AB, one in two. Of course, if one knows the group of the child and of the mother, other figures are

Read before the Section on Miscellaneous Topics, Session on Forensic Medicine, at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.
1. von Dungern and Hirschfeld, Ottenberg.

2. Hooker, S. B., and Boyd, W. C.: *J. Immunol.* 16: 451 (May) 1929. Wiener, A. S.: *J. Immunol.* 24: 443 (June) 1933. For the population of Germany the figure is somewhat higher; namely, about 1/6.

The results of family investigations carried out by several independent workers are summarized in table 5. As is seen from the table, the observed frequencies agree satisfactorily with the calculated values and there are only a few apparent exceptions to the theory, such as must be expected on account of illegitimacy. That this assumption is correct is supported by the fact that in seven of the eight cases the incompatibility certainly involves the father and not the mother. Most likely the same holds true for the remaining case.

A convincing argument is afforded by a study of the properties M and N in mothers and children. This

TABLE 4.—Type of Children from Six Matings

Types of Parents	Per Cent Children of Types		
	M	N	MN
M × M.....	100	0	0
N × N.....	0	100	0
M × N.....	0	0	100
M × MN.....	50	0	50
N × MN.....	0	50	50
MN × MN.....	25	25	50

test for the accuracy of the inheritance theory is based on the second rule, according to which incompatibility can be recognized when the type of only one parent is known. In fact, in the data thus far collected, including more than 6,000 children and their mothers, there is no case of a mother of type M having a child of type N or a mother N with a child M. Additional evidence was provided by the examination of twins, who, when identical, always agree with regard to the properties M and N and belong to the same blood group.

Further confirmation was obtained by a statistical method similar to that which led Bernstein to his "three gene" theory of the heredity of the blood groups. If the relative frequencies of the genes M and N in a population are designated by the letters m and n, respectively, then, a priori, $m + n = 100$ per cent. Since type M, corresponding to genotype MM, possesses two genes M, its frequency in a homogeneous population is m^2 . Hence $m = \sqrt{M}$, where M represents the observed frequency of type M in the population. Similarly, $n = \sqrt{N}$, so that $\sqrt{M} + \sqrt{N} = 100$ per cent.

In fact, in all trustworthy investigations on the distribution of the properties M and N in various populations it was found that, if one adds the square root of the frequency of the types M and N, the sum is approximately equal to 100 per cent. As a striking example, Schiff's figures obtained by the examination of 1,420 inhabitants of Berlin may be cited; namely: M 0.301, N 0.208; MN 0.49; in this case $\sqrt{M} + \sqrt{N} = \sqrt{0.301} + \sqrt{0.208} = 0.549 + 0.457 = 1.006$.

On the basis of the studies discussed, European authors concur in advocating the tests for M and N as evidence in affiliation cases, and these tests have actually been applied in Germany, Denmark and Sweden in several hundred lawsuits. The chances of excluding paternity are considerably increased by the use of this method, so that when, in addition to blood grouping, tests are made for M and N, one out of three wrongly accused men will be exonerated. Likewise, the chances for detecting interchange of new-born infants in hospitals are raised to about 70 per cent. It must be emphasized, however, that great caution should be employed in the performance and in the interpretation of the tests, particularly those for the property N, and that there are questions concerning the technic of these

tests which still require thorough study in order to exclude possible mistakes.⁷

To turn now to the second forensic application of blood grouping, namely, the examination of blood stains,⁸ it may be said that these tests, though not often required, prove to be of considerable consequence in certain criminal court proceedings. After having established by chemical tests that the stain contains blood and by means of the precipitin reaction that it is of human origin, one may use two methods, the examination for iso-agglutinins and that for agglutinogens. The test for agglutinins consists in adding a trace of the dried blood or a fragment of the stain or an extract of it to suspensions of bloods of the groups A and B. If possible, the tests should include the blood of the victim and the accused person. Precautions must be taken in order to avoid errors due chiefly to the presence of agglutinating substances other than iso-agglutinins or to pseudo-agglutination. For this reason control tests with blood of group O are essential.

As a rule, the iso-agglutinins are still active in dried blood after many months or even a longer interval, but they may deteriorate sooner and consequently no conclusions can be drawn from negative reactions. The iso-agglutinable substances of the cells are more resistant than the iso-agglutinins and may be demonstrable when the other method fails. After drying, the red cells cannot be used for agglutination tests; but they still are capable of combining with the corresponding agglutinins. Hence, if on adding serum of group A and of group B severally, or a mixture of both to the material to be examined, iso-agglutinins are absorbed, it is possible in this way to determine the group of the dried blood.

Cases that prove the value of the group diagnosis of blood stains have been reported by several authors, especially Lattes⁹ and Popoff.¹⁰ In some instances it was established that a blood stain found on the clothes or an implement of the suspected individual did not

TABLE 5.—Summary of the Studies of Landsteiner-Levine, Wiener-Vaisberg, Schiff, Thomsen, Clausen, Lattes, Blaurock and Crome

originate from the victim, whereupon the accused was discharged; in other cases the testimony offered by the defendant was shown to be false. It has been justly advised, therefore, by Merkel, that whenever an autopsy is made on the victim of an assault the blood group of the body should be determined for possible future use.

The reactions for M and N have thus far been utilized for the examination of blood stains in only a few legal cases,¹¹ but a more general application may be expected as the methods are improved.

7. Compare Koller: *Ztschr. f. Rassenphysiol.* 5: 102, 1932.

An extension of the blood group tests was made possible when it was found by several authors that the properties A and B are detectable by suitable technic not only in blood and organs but also in secretions such as saliva, seminal fluid, mucus and sweat. Thus, in some cases the blood group could be determined in traces of seminal fluid and in the small quantity of dried saliva on the edge of an envelop or on cigaret stubs. On the other hand, the presence of group specific substances in secretions renders it necessary to take precautions in the examination of blood stains; that is, to test in addition to the stains other parts of the material not soiled by blood.

It is of interest that, depending on the presence or absence of group specific substances in urine and saliva, two types of individuals can be sharply distinguished, for these substances are practically lacking in the secretions of from 20 to 30 per cent of all individuals. Still more remarkably, the ability to secrete the group substances is inherited as a mendelian dominant.¹²

Attempts to demonstrate the agglutinogens M and N in secretions and organs have not been successful.

It is not practicable here to enter into the question of technic and in regard to this I must refer to the treatises and papers on the subject. Suffice it to say that particularly the tests for M and N and the examination of blood stains are of a delicate nature and require a worker with considerable experience and acquainted with the pertinent literature. As to the prospects of the forensic application of the blood tests in this country it will, of course, depend on whether the available evidence will satisfy the legal authorities as it has the European courts.

Rockefeller Institute for Medical Research.

ABSTRACT OF DISCUSSION

DR. ALEXANDER S. WIENER, Brooklyn: In my studies on the heredity of the agglutinogens of human blood, specimens of the blood of 1,334 mothers and their 1,462 children were examined for the properties A and B, and a series of 461 mothers with 495 children for the properties M and N. In addition, the simultaneous heredity of the four agglutinogens A, B, M and N was also studied in 131 complete families with 642 children. The results of these investigations have convinced me firmly of the reliability of the tests. The method cannot be applied in every case, since it exonerates only one out of three falsely accused men. Another opportunity for applying the method arises when two new-born infants are interchanged, as happened in a Chicago hospital in 1930. In this case the tangle was straightened out with the aid of the classic blood groups, since, whereas neither child's blood group matched, in accordance with the laws of heredity, with the blood groups of the parents to whom they had been assigned, the bloods matched satisfactorily when the children were exchanged. If only the four Landsteiner blood groups are tested for, the accused man has one chance in six or seven of establishing his innocence. The discovery by Landsteiner and Levine of the properties M and N and their mode of heredity is a very important advance, since it has doubled the number of cases in which a definite decision can be made. Perhaps the most convincing demonstration of the value of the blood grouping tests is afforded by the reaction of the mother when confronted with the results of the examination. Thus, in a case tried before the court of common pleas of New Haven, Conn., a woman accused a certain man of the paternity of her illegitimate child. I examined the blood of the individuals involved and found that the woman belonged to group O, the man to group A, and the child to group B, so that the accused man could not possibly have been the father of

the child. When the mother was confronted with the results of the examination, she withdrew her charge and the man was acquitted. In many cases of disputed paternity, the use of blood grouping tests is in the child's interest. Thus, the husband may be appeased if the exclusion of the other man by these tests proves that his suspicions are unwarranted; or the accused man in a bastardy case may be induced to marry the mother of the child, if he is not excluded by the blood tests. An important legal question is whether the court has the power to order the individuals involved in a filiation case to submit to a blood test. Lee states that "in this country the right to have a physical examination includes the right to have a drop of blood where it is material." And in reply to the argument that the medical examination is a violation of the privilege of refusing to testify on the ground of self incrimination, Lee remarks, "What is required of the witness is not testimony but physical inspection, something in the nature of real evidence."

DR. KARL LANDSTEINER, New York: I want to emphasize once more the difficulty of the technic and the danger of faulty results, and especially that one should refrain from giving a definite opinion if the results of the tests are not clear cut.

THE TONSILS, THEIR FUNCTION AND INDICATIONS FOR THEIR REMOVAL

L. W. DEAN, M.D.

ST. LOUIS

A study of the tonsil problem requires a consideration of all the lymphoid tissue in the pharynx. The palatine tonsils are, on a clinical basis, the most important of the lymphoid structures in the throat. However, the other lymphoid masses may be and usually are involved in throat infection. They must be given serious consideration if the influence on systemic disease of infection about the throat is to be eradicated. Certainly in removing the conditions about the throat that have a deleterious influence on such diseases as rheumatic fever, heart disease, Still's disease, chorea and hemorrhagic nephritis, it is impossible to get the most satisfactory result by confining the attention to the palatine tonsils or to these structures plus the pharyngeal tonsil. If in this class of cases following the removal of the pharyngeal and palatine tonsils the children suffer from acute exacerbations of their systemic disease, and if, as is usually the case, the acute exacerbations are preceded by acute upsets in the upper respiratory tract, one must realize that there is some condition about the throat, nasal sinuses or ears that is responsible for these acute disturbances of the upper respiratory tract.

It is a common thing for the pediatrician to say "When you removed the faueial and pharyngeal tonsils from this child with a heart lesion, you did not eradicate all the foci of infection because the child is suffering from acute upper respiratory upsets. Further, these attacks are having a deleterious effect on the heart."

In every case in which a tonsil is removed for the purpose of benefiting a systemic condition, my associates and I make a note in the chart to the effect that we have done what should meet the exigencies of the situation but that it is not certain that all chronic infection has been removed. Further, we request that the patient be returned for reexamination in the event that

From the Oscar Johnson Institute, Department of Otolaryngology, Washington University School of Medicine.

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

12. Schiff, F., and Sasaki, H.: *Klin. Wchnschr.* 11: 1426 (Aug. 20) 1932.

the clinical course of the disease suggests that there is something left in the upper respiratory tract which has a deleterious influence on the patient.

It is usual for children to be returned for further study. They may be returned several times. We get the best results by adding our supervision to that of the pediatrician for from eighteen months to two years. It is only by this thorough cooperation that the best results can be secured. It is irritating sometimes to have the pediatrician insist that a condition has been left in the regions of the upper respiratory tract which if removed will benefit the child. My experience has been that his judgment was correct. The opinion of the internist or pediatrician is of greatest importance in deciding the type of operation, if any, that should be done on the lymphoid tissues of the throat.

The most important part of the treatment of heart disease, rheumatic fever, arthritis or chorea in children is the eradication of chronic infection about the upper respiratory tract. It is axiomatic that the lymphoid masses in the throat, other than the palatine and pharyngeal tonsils, may be infected and consequently must receive attention in the control of the infection about the throat. It is also true that one cannot possibly remove from the pharynx every vestige of infected lymphoid tissue, but much more can be done than the removal of the faucial and pharyngeal tonsils. The course of the systemic response is an important factor in determining how thorough one's work has been.

The tonsils and other lymphoid structures of the throat are not lymphatic glands. Neither is their structure the same as that of the lymphoid tissue of the spleen and bone. They are a part of the subepithelial lymphoid tissue of the body. The lymphoid structures of the pharynx are integral parts of the pharyngeal mucous membrane. This lymphoid tissue is laid down in the mucous membrane of the pharynx as it develops. Even the palatine tonsils are first folds of pharyngeal mucous membrane. These appear early in embryonic life, the lymphoid tissue making its appearance in the fold at a later date. The tonsils consist of reticulo-endothelial supporting tissue and lymphoid tissue with and without germ centers. It is no different from the lymphoid tissue in the alimentary tract. The tonsils differ from the lymphoid glands in at least one outstanding feature; namely, they possess no afferent lymphatic vessels, and consequently the lymph stream must always flow from the periphery of the mass.

In addition to the palatine tonsils the other lymphoid structures of the pharynx that have clinical significance are the pharyngeal tonsil, the lingual tonsil, the so-called infratonsillar nodes, which lie just below the palatine tonsils, and the macroscopic lymph masses in the mucous membrane.

In simple hypertrophy without infection, the pharyngeal tonsil is of greater clinical significance than the palatine tonsils, because of its location. Its enlargement may easily interfere with nasal respiration.

The palatine tonsils are the outstanding sources of infection. Their crypts are long and bifurcated. They are often constricted at the opening into the pharynx. No mucous glands open into the bottom of these crypts. Anatomically they are particularly well fitted for the retention of debris such as desquamated epithelial cells and bacteria. The crypts in the lingual tonsil are short and wide and their openings are funnel shaped. They do not easily become harborers of debris. The pharyn-

geal tonsil and the infratonsillar nodes also contain crypts which become impacted with debris more readily than those of the lingual tonsil and much less easily than those of the palatine tonsil. So far as I know the follicles on the wall of the mucous membrane do not contain true crypts. They do contain the same type of lymphoid tissue as is found in the palatine tonsil; namely, the germinal centers and lymphoid tissue without germinal centers. Because of these structural characteristics the lymph follicles and the lingual tonsil are less often the focus of infection, while the palatine tonsils are the greatest offenders. Nevertheless, in my lifetime I have seen many cases of diseases such as arthritis and glomerular nephritis, which were controlled only by the eradication of infection in the lingual tonsil, and there has been an occasional case in which a satisfactory result was secured only by getting rid of the macroscopic lymphoid follicles in the mucous membrane of the pharynx. In rheumatic fever, heart disease and other conditions the patient may be benefited by the removal of the palatine and pharyngeal tonsils, but a satisfactory result is not secured. Under these circumstances one cannot afford to overlook the lingual tonsil, the infratonsillar nodes and other lymphoid masses in the wall of the pharynx. It is only by repeated examinations of the throat and the careful eradication of these minor sources of infection that the best results are obtained.

This contribution does not consider the nasal sinuses and the ears, which are the other sources of infection about the upper respiratory tract.

The infection of the lymphoid masses of the pharynx is not the cause of rheumatic fever, heart disease, chorea or Still's disease. This can be amply demonstrated by the fact that, while the removal of faucial and pharyngeal tonsils may decrease slightly the incidence of rheumatic fever and heart disease, it certainly does not prevent it.

In toxic malnutrition, secondary to infection of the lymphoid masses in the pharynx, the infection is the outstanding cause. Given a case of malnutrition secondary to infection about the throat with such symptoms as emaciation and interference with growth, if this infection is eradicated there is often a miraculous return to the normal. The weight increases, the height progresses and the child soon becomes normal so far as weight and height are concerned. This is not the case in rheumatic fever, heart disease, chorea or Still's disease. In children with these diseases, eradication of all the infection about the upper respiratory tract will be followed by a period of months or perhaps two years before the child returns to normal. Only by eradication of all infection plus dietetic, hygienic and other kinds of treatment is the desired result secured.

A child with rheumatic fever and no infection about the upper respiratory tract may develop fever which can be controlled by the use of salicylates. This is not the case when the fever is the result of infection of the lymphoid tissue. In short, one must be careful not to assume that tonsillar infection causes many of the systemic diseases that are associated with this condition; rather, one should assume that there is a systemic disturbance which is seriously affected by infection of the lymphoid tissue in the pharynx. This does not invalidate in any way the statement, made earlier in this paper, that the primary consideration in the treatment of many of the systemic conditions is the eradication of infection about the upper respiratory tract.

The removal of the larger masses of lymphoid tissue in the pharynx early in childhood does decrease markedly the incidence of scarlet fever, common colds and otitis. It decreases somewhat the incidence of rheumatic fever, chorea and heart disease in children. It is particularly beneficial in reducing the incidence of cervical adenitis. In my experience the removal of these masses has not decreased the susceptibility to diphtheria. However, the absence of pharyngeal and faucial tonsils favorably influences the course of the disease. There has been much discussion of the excellent work done by Kaiser on the increased incidence of laryngitis, bronchitis and pneumonia in tonsillectomized children. After a serious consideration of this investigation extending over a period of several years, I am convinced that the increased incidence of these pulmonary conditions in tonsillectomized children is due to the fact that, at the time the tonsil operation was performed, nasal sinusitis was present and it is this nasal sinusitis which is responsible for the pulmonary disease.

Because of the importance of determining all sources of chronic infection about the upper respiratory tract in children with such diseases as rheumatic fever, chorea, hemorrhagic nephritis and Still's disease, I always make an examination of the nasal sinuses at the time of the tonsil operation in this class of cases. I do this because the work can be done more advantageously in very young children under general anesthesia. It is the rule to find some suppurative sinus disease. Most of these conditions are controlled by dietetic and hygienic treatment following the tonsil operation. However, many of the sinus infections persist and are important factors in the production of pulmonary disease. I think this question can be definitely answered only by studying the incidence of pulmonary disease in a group of children free of nasal sinus disease that are not tonsillectomized and in a second group of children free of nasal sinus disease at the time of the tonsillectomy.

As will be noted later in this contribution, the lymphoid masses of the pharynx have a decidedly important physiologic function. They should not be removed in children unless the deleterious results of the infected tonsils overbalance the good results of the physiologic action of these structures, or, I may add, the physiologic function has been so seriously interfered with by the infection that their defense reaction has been impaired or lost.

Various functions have been given to the tonsils. The tonsillar crypts are said to be tubes, similar to test tubes, in which organisms develop producing toxins which are absorbed and result in autoimmunization. Waldapfel thinks that they are concerned in filtering out particulate matter from the blood stream. They are said to produce lymphocytes and undoubtedly do produce lymphocytes if they are needed. It has been said that they react against stimulants, bacteria and toxins which penetrate into the lymphoid tissue. Certainly they develop after birth and continue to function until after the age of puberty, when involution occurs. They are said to produce hormones and to furnish digestive ferments.

There is no agreement among physiologists as to the function of the tonsils. I do not know what their function is. The lymphoid tissues of the body are all actively functioning in infancy and in early childhood and they continue to function until involution occurs. I do not know the reason for the involution, but I think it may be assumed that before it occurs the tonsils have

performed their main function. In early childhood, very slight infection causes these structures to enlarge. The spleen is easily increased in size, the glands of the neck become hypertrophied easily; it is not unusual at this age to have even the lymph nodes over the mastoid enlarge. Later in life these appear only with pediculosis or with some infection of the scalp or mastoid.

The tonsils as well as other lymphoid structures enlarge easily. Repeated infections, repeated colds, dietary disturbances, endocrine disturbances and toxemias all have a tendency to increase the size of these structures, often without any manifest infection of the lymphoid tissue. There can occur a familial non-inflammatory hypertrophy of these structures, sometimes accompanied by dental caries, both undoubtedly being due to some dietetic or endocrine disturbance. It is not necessary to have infection of the tonsils to get these simple hypertrophies.

To me it is certain that the tonsils in infancy and early childhood are a part of the defense mechanism of the body. They protect the organism against those factors which cause them to become acutely swollen. Repeated irritations with swelling do cause simple hypertrophy of these structures. When the tonsils undergo involution at the age of puberty they lose their function.

Rules cannot be made to determine whether or not tonsils should be removed. Each case presents its own problem. The good judgment of the physician must decide in each case just what should be done. He must take into consideration the local conditions, the condition of neighboring structures and the general condition of the patient. Even then, particularly in adults, it is often a gamble as to the results to be secured by tonsillectomy.

It is my custom to tell adults with chronic systemic diseases that may be favorably influenced by the removal of the tonsils that I cannot definitely predict the result. I am influenced very much by the opinion of the internist and we often decide on the basis of probabilities to take the tonsils out. Naturally we are influenced by anything in the history which connects the tonsils with the systemic disease. The tonsils play a much more important rôle as a source of infection in children than in adults; the average result in children is much more satisfactory than in adults.

In cases in which infection of neighboring structures, as the middle ear, nasal sinuses and glands of the neck, can be traced to infection of the tonsils, removal of the latter is indicated. The infection not only spreads through the lymph vessels draining the tonsils but it spreads along the perivascular lymphatic spaces sometimes contrary to the direction of the blood stream. The jugulodigastric lymph gland, lying on the internal jugular vein where it is crossed by the digastric muscle, is more often swollen in infection of the palatine tonsils than the other glands. Its swelling suggests that microorganisms are entering the lymph stream from the tonsils. However, a carious tooth may produce the same result. Its enlargement when due to tonsillar infection suggests that the tonsil is a menace to the body.

Rarely, quiescent tuberculosis of the tonsils is found. This is much less common in my experience today than it was twenty years ago. Tuberculous glands of the neck may be associated with such tonsils. Other conditions cause tuberculous and pyogenic infections of

the glands of the neck, and the fact that there is present an infected tonsil does not mean that it is the cause of the adenitis.

The fact that a tonsil is chronically inflamed without any evidence of local or systemic disturbance is not sufficient reason for its removal. I grant that I have advised against the removal of such a tonsil and the patient has developed an acute tonsillitis a few months later with acute arthritis. This was his first attack of acute tonsillitis. Naturally if a tonsil is present it can become acutely infected, but that is no reason for removing all tonsils.

I have convinced myself by meticulous observations, each covering a period of years in two large training schools for nurses, that the routine removal of faucial tonsils in probationers is a justifiable procedure. An undergraduate nurse, however, is particularly liable to develop acute tonsillar infections. In spite of all precautions, nurses do get ill at the times when the hospitals are crowded. This results in overwork of the nurse as well as of the doctor; outdoor privileges may be curtailed and the weather may prevent proper exercise at a time when the nurse is exposed to the most virulent infections. In an official report to the governing board of a hospital the statement was made that the routine removal of tonsils in probationers had so decreased the incidence of sickness that the financial aspect of the institution was improved. Doctors, nurses and dentists present more indications for the removal of their tonsils than those not so often exposed and overworked during the periods of epidemics.

Simple hypertrophy of the tonsils may demand their removal in order to get normal breathing. Familial hypertrophy of the lymphoid tissues of the throat may occur without macroscopic evidence of infection. Some of these tonsils show no more evidence of infection on microscopic examination than the most normal tonsils. Sometimes children with this condition have carious teeth, as in a group studied by Dr. McCulloch in our service. Hyperplasia of the tonsils, hyperplasia of the other lymphoid tissues of the body and carious teeth go together. Enlargement of the spleen, carious teeth and simple hypertrophy of the tonsils are found in rickets. Many of the hypertrophied tonsils are not macroscopically inflamed even in the presence of malnutrition and carious teeth. This suggests that they combat infection or at least are very resistant to it. The great improvement in breathing in these children after the removal of faucial and pharyngeal tonsils certainly justifies the interference with the physiologic action of the structures removed. There is no reason to think that the remaining lymphoid tissue in the pharynx does not meet the exigencies of the situation. Tonsillotomy leaves the remaining scarred tonsil tissue a menace to the individual.

The removal of macroscopically normal tonsils and hypertrophied tonsils with no evidence of infection has favorably influenced cases of hemorrhagic nephritis, uveitis or rheumatic fever. A number of pediatricians, internists and otolaryngologists decided that a pair of faucial tonsils appeared to be perfectly normal. It was the unanimous opinion that they should be removed because of a nephritis. They were removed with benefit to the patient. Consequently it is evident that the general condition of the patient has much to do with the decision as whether or not to remove tonsils.

Given a patient with a systemic condition that is often favorably influenced by the removal of infected

tonsils and perfectly normal looking tonsils, I feel that the tonsils should be removed, particularly if the condition refuses to yield to other forms of treatment. To put it more plainly, I think that if a patient has hemorrhagic nephritis, a heart lesion, a rheumatic fever or a uveitis which continues active in spite of every effort to make it quiescent, this condition in itself is an indication for the removal of these lymphoid structures. Certainly by carrying out such a procedure, the cases in which satisfactory results are obtained greatly outnumber the cases in which such results are not secured. The seriousness of the conditions under consideration justify this procedure.

The apparently normal tonsils that we have removed because of a systemic disease have been examined microscopically. In every instance chronic infection involving the epithelium was found deep down in the crypts. The evidence of infection found in the crypts is a leukocytic infiltration of the epithelium and underlying lymphoid tissue with some destruction of the protective epithelium. In some cases in which the tonsils have been removed because of simple noninflammatory hypertrophy such areas have not been found.

If judgment is based on the systemic condition of the patient, one must be careful not to remove the tonsils when the condition has progressed to such a stage that it is impossible for the removal of infected lymphoid tissue to exert a favorable influence. Tonsils should not be removed because of the presence of so-called chronic chorea, in which the contractions are due to an unstable nervous system and are not due to true chorea. In the same way in nephritis, the disease may progress to a stage at which the pathologic changes in the kidney are such that it will not be influenced by the removal of the tonsils. In dealing with chronic arthritis one must be certain that the pathologic condition is such that it will probably be benefited by the eradication of a focus of infection. It is necessary in these cases to have the most intimate cooperation between the pediatrician or the internist and the laryngologist. The determination as to whether or not the tonsils should be removed is often dependent on the ability to prognosticate that a systemic condition will probably be influenced by the eradication of infected lymphoid tissue. Certainly there is need of doing this when the systemic condition is deleteriously influenced even by the mildest acute attacks of pharyngitis.

I cannot say that any tonsil is not the seat of chronic infection except after removal and microscopic study. Study in the laboratory has shown definite evidence of infection in the most innocent looking tonsils. The history of acute tonsillitis is a more reliable indication of chronic infection than the appearance of the tonsil.

I do not like to remove palatine tonsils under the age of 2 years. There are two reasons for this: first, this is the age during which the tonsillar function is most important; second, the operation at this age is more serious than later. If however, there is a definite indication for the removal of the tonsils, it should be done. If an infant suffers from attacks of acute tonsillitis and if with one attack it develops a lobar pneumonia which improves only with an improvement in the throat condition, it would be hazardous to leave the tonsils in. Adenoids blocking the nasopharynx may be removed at any age.

Practically, the removal of tonsils is always a gamble. Even if they are infected it is not necessarily true that they are the focus for systemic disease. In most cases

in which I have urged the removal of the tonsils, except in instances with definite local indications, they were removed on the basis of chance. If the patient thoroughly understands this before the work is done, there will be many fewer complaints regarding the needless removal of tonsils. Excluding the immediate deleterious effects of the tonsil operation such as lung abscess and infection of the cervical glands, in my own service I have yet to encounter the first case in which I or the family felt that there resulted any permanent deleterious effect from the tonsil operation.

Rules cannot be laid down for the practice of medicine. There are a multitude of factors bearing on the question as to whether or not tonsils should be removed. The judgment must rest with the individual after a thorough study of the case. If this is most carefully done, the patient need not worry about having a deleterious result from the removal of these structures.

ABSTRACT OF DISCUSSION

DR. FRANK R. SPENCER, Boulder, Colo.: Some of the indications that are less frequently mentioned are as follows: 1. Impaired hearing made worse by each acute attack of tonsillitis even though the attacks are rather mild and in themselves might not attract attention. I do not believe the impaired hearing is likely to be made normal by the operation, but the progress of the disease may be stopped. 2. Acute or chronic infection of the tonsils in patients with goiter. Dr. Joseph C. Beck was one of the first to call attention to this. 3. Sinusitis in children which doesn't respond to treatment and in children with infection and enlargement of the tonsils which may not be marked enough to demand an early tonsillectomy. I am familiar with the argument that the removal of the tonsils in children with sinus disease is often contraindicated. Perhaps in some patients it is, but I do not entirely agree with this principle. The infection in the tonsils is only another straw added to break the camel's back. Such children may recover from the sinus disease without sinus surgery if the tonsils and adenoids are removed. 4. Chronic suppurative otitis media, especially when aggravated by acute or chronic infection of the tonsils. 5. Bronchiectasis aggravated by acute or chronic tonsillitis. 6. Chorea, often improved by early tonsillectomy before the chorea becomes chronic. I know little about the function of the tonsils. However, I try to avoid removal of the tonsils in children under 4 years of age unless forced to do so by definite indications. The tonsils and adenoids may have some physiologic function as ductless glands in infants and young children up to 4 or 5 years of age. This has not been proved, but it is substantiated by clinical observation. A few of these children change after operation as if suffering from hypothyroidism. The tonsils may have a protective function similar to that of the reticulo-endothelium. Furthermore, after tonsillectomy in children the lymphoid tissue over the lateral pharyngeal wall enlarges sometimes. This enlargement may assume serious proportions and resemble a piece of tonsil. It may harbor infection and call for cauterization or coagulation. Swabs and cultures of the tonsils give little practical information because of the great variety of germs found and the extreme variation in virulence. I pay little attention to the bacterial indications except when the diphtheria bacillus is reported. I approve of Dr. Dean's "follow up" system for two years after operation to determine end results. This gives added authority to his mature conclusions.

DR. EDWARD CLAY MITCHELL, Memphis, Tenn.: In cases in which there are large, diseased tonsils and adenoids productive of difficult breathing their removal is indicated. The hypertrophied tonsil with no history of disease should be left alone. Recurrent tonsillitis is often seen when the first attack would be quite severe, classified probably as class 4; the next attack would be much lighter, the third attack still lighter, and the child probably would have no further tonsillitis, showing perhaps that he had developed some immunity. In discussing the tonsils as a focus of infection, three factors should be thoroughly studied. First, is the tonsil the sole cause of the

condition? Second, will the removal of the diseased tonsil cure the systemic condition? Third, when should the diseased tonsil be removed? Rheumatic fever is one of the most common conditions in which the tonsil is blamed. Other common systemic infections in children when the tonsil is spoken of as the offending factor are kidney conditions such as nephritis, particularly of the acute glomerular type, pyelitis and enuresis. For all these conditions the tonsil is being removed, sometimes with benefit and in many instances with no improvement. There is much controversy as to whether the tonsil should be removed in the acute glomerular nephritis while the upper respiratory condition is still acute, when nephritis does not improve under proper treatment. In my experience many times rapid improvement has been shown when the focus of infection was eradicated even during the acute stage. Of course, I recommend waiting until all the acute symptoms have subsided when possible. In a symposium held by the American Academy of Pediatrics, the statement was made that cyclic vomiting in 50 per cent of the cases was markedly improved by a tonsillectomy. However, it would seem to me that age incidence plays a part. Tonsillectomy has been recommended for dullness and inattention in school, particularly where the adenoid symptom is manifest. In a large series of cases Kaiser found the sedimentation time markedly increased following tonsillectomy. His average patient lost 2 pounds following tonsillectomy. Hemorrhages can largely be prevented by careful consideration and examination of the child before the operation. I should like to ask whether the paranasal sinusitis is more common after tonsillectomy. In the younger child I sometimes find no history of tonsillitis but very large tonsils and enormous adenoids that interfere with breathing. It is often the question as to whether only the adenoids should be removed and the tonsil left. I believe that the healthy tonsil should remain and only the offending adenoid removed. Should small stubs of tonsils left from a former operation be removed? Another type of patient seen is the child who presents himself with definite paranasal sinusitis, likewise diseased tonsils and adenoids. Should the tonsils and adenoids be removed and the sinuses drained at the same time?

DR. VIRGIL J. SCHWARTZ, Minneapolis: Waldapfel finds that when bacteria are introduced, through even slight injury, into one inferior turbinate, they traverse the venous, not the lymphatic, channels of the nose and pharynx to reach the tonsils and are eliminated into the crypts. Scherf finds that pigments such as India ink, after injection into the carotid artery, are excreted through and can be demonstrated in the tonsils. They think, therefore, that the tonsils assist in removing foreign material from the blood stream. Heiberg sponsors a second theory, that the germinal centers of the tonsils destroy lymphocytes while other parts of the tonsil produce lymphocytes. Schmidt believes that these destroyed lymphocytes liberate an endolysin, which may reach the general blood stream to produce a sudden leukopenia. Hoepke thinks that in the normal tonsil the germinal centers produce lymphocytes but that when irritated by toxic or inflammatory substances they produce phagocytosing reticular cells. Kelemen found that, whereas ordinary leukocyte extract promotes the growth of fibroblasts and other cells in culture, tonsil extract prevents their growth. The latter also may inhibit growth in guinea-pigs. Wolffheim proposed a fourth theory, that children's tonsils and other lympho-epithelial structures, including Peyer's patches and the appendix, are the principal site of the occult immunization of the body against infectious organisms that enter the digestive and respiratory tracts. Digby, too, inclines toward this view of continuous autovaccination. Bacteria, he thinks, on or near these lymphoid structures are attracted by positive chemotaxis through the epithelium into the lymphoid nodule. The bacterial attack is usually repelled by the development of a great excess of special lymphocytes, opsonins, bacteriolysins and other immune substances, which enter the general system and so reduce the danger of bacterial infection elsewhere. I am certain that some of the laryngeal and bronchial irritations which appear to be more common after tonsillectomy than before are not inflammations at all but allergic manifestations that were not recognized at the time the tonsillectomy was performed. Tonsil examination should always begin with palpation of the deeper glands of the neck, the anterior of which, lying beneath the

anterior margin of the sternomastoid muscle, may stand alone as incriminating evidence against the tonsil which it drains. The incidence and course of scarlet fever and diphtheria are greatly benefited by tonsillectomy. Children who have pathologic tonsils and develop a contagious disease must combat not only the latter but often also an acute, severe tonsillitis with all its potential complications, such as acute adenitis, or otitis. The latter are the sequelae of the tonsillitis rather than of the contagious disease.

D. L. W. DEAN, St. Louis: In familial hypertrophy the tonsils usually cause trouble by interfering with breathing. With familial hypertrophy of the tonsils there almost always is caries of the teeth. In rickets there are an enlarged spleen, caries of the teeth and noninflammatory hypertrophy of the tonsils. All three conditions are probably due to deficient diet or endocrine disturbance. The fact that in familial hypertrophy of the tonsils there are caries of the teeth and noninflammatory hypertrophy of the tonsils suggests that the lymphoid tissues of the pharynx combat infection. There is usually no history of tonsillitis. It is almost impossible to control the caries of the teeth without getting rid of the tonsils, which are blocking the pharynx. Trimming the tonsils is a bad thing because the crypts are constricted by scar tissue and become a potential focus of infection. Some twelve years ago I made routine observations on all tonsils removed for a period of two years and found that about 2 per cent presented latent tuberculosis. This condition could not be diagnosed except by microscopic examination of the tonsil after the operation. Now I see only about one case or two cases at the most in a year that show microscopic evidence of latent tuberculosis of the tonsils on routine examination. I think this is due to the improved supervision of the milk supply of Saint Louis. In a pharyngeal tonsil that was removed because of phlyctenular conjunctivitis, there were two areas of caseation in the tonsil. Acid fast organisms were scattered throughout the lymphoid tissue of this mass. This pharyngeal tonsil presented, on clinical examination, nothing except the evidences of moderate simple hypertrophy. It was removed because the patient had phlyctenular conjunctivitis. The conjunctivitis did well after the removal of this latent tuberculous lymphoid mass. I do not like to remove palatine tonsils under the age of 2 years, for two reasons: First, this is the time when the tonsil function is more important; second, the operation at this age is more serious than later. If, however, there is a definite indication, they should be removed. If an infant suffers from attacks of acute tonsillitis and if with one attack it develops a lobar pneumonia which improves only with the improvement in the throat condition, it would be hazardous to leave the tonsils in. If this occurs in midwinter and the weather is not favorable for the removal of the tonsils, I fear another attack of tonsillitis and pneumonia. Adenoids blocking the nasopharynx may be removed at any age. Practically, removal of tonsils in an adult for systemic conditions is always a gamble; it is less so in children. Even if in the adult they are infected, it is not necessarily true that they are the focus for systemic disease. In most cases in which I have urged the removal of tonsils, except when there were definite local indications for their removal, they were removed on the basis of chance.

Primary Malignant Tumor of Bone Marrow.—Multiple myeloma may be defined as a primary malignant tumor of bone marrow characterized by multiple foci in long and flat bones of the skeleton and usually associated with anemia, Bence-Jones proteinuria, rare metastasis and a fatal termination. MacIntyre described the condition in 1850, but von Rustizky first recognized it as a specific disease of the bone marrow, and referred to it as myeloma. Kahler, in 1889, called attention to the associated proteinuria, hence the reference in the literature to "Kahler's disease." Geschickter and Copeland, in 1927, reviewed 425 cases from the literature, and stated that multiple myeloma was present in only 0.03 per cent of all malignant conditions. Symmers found only three cases of the condition in the course of 6,000 postmortem examinations performed at Bellevue Hospital, New York City. Thus the rarity of multiple myeloma is evident.—Slavens, J. J.: Multiple Myeloma in a Child, *Am. J. Dis. Child.* 47:821 (April) 1934.

ANTITOXIN VERSUS NO ANTITOXIN IN SCARLET FEVER

PASCAL F. LUCCHESI, M.D.

AND

JAMES E. BOWMAN, M.D.

PHILADELPHIA

Much has been written during the past few years on the use of scarlet fever antitoxin in the treatment of this disease. Many prominent physicians, such as Veldee, Stevenson and Mitchell,¹ Winkel,² Lichtenstein,³ and Gordon,⁴ supported by considerable personal experience, proclaim with great emphasis that when scarlet fever antitoxin is administered early and in sufficient quantity there follows a decline in the fever, a reduction in the number of febrile days and a decrease in the incidence of complications. On the other hand, just as many physicians of equal prominence and experience, as Toomey and Dolch,⁵ Gabriel⁶ and Rolleston,⁷ disagree in part or in toto with these observations. Toomey believes that the slight amount of good noticed in the use of this antitoxin is counterbalanced by the ill effects produced in the occurrence of serum disease. We have therefore set out, without any fixed opinion to study a group of 5,377 records of scarlet fever patients admitted to the Philadelphia Hospital for Contagious Diseases during the years 1927, 1928 and 1929. These years were selected only because they represent the first three years of the use of antitoxin at this hospital. We had no part either in the selection of the patient or in the amount of antitoxin to be given. As a matter of fact, antitoxin was given to all patients who were not hypersensitive to this serum. The antitoxin used was purchased from different manufacturers; consequently it varied greatly as to concentration and protein content. Every patient was skin tested for sensitivity to the antitoxin. Those found positive were treated symptomatically. They formed a large number of the control group. Because of the variations in the types of scarlet fever, it was decided to subdivide the patients into groups that would denote the severity of the disease. Accordingly, cases in which the temperature did not exceed 100 F. by mouth were classified as mild; those in which the temperature was over 100 F. but did not exceed 102.5 F. as moderate, and those in which the temperature exceeded 102.5 F. as severe. Thus the 5,377 cases were divided into 1,162, or 21.6 per cent mild; 3,158, or 58.7 per cent moderate, and 1,017, or 18.9 per cent severe.

In view of the controversy that exists on the frequency and virulence of serum disease, this angle was likewise studied. Some of the patients in the serum group received ephedrine, while others received ephedrine and calcium, with the hope that the effect produced on the incidence of serum disease might be noted.

EFFECT OF ANTITOXIN ON THE DURATION
OF FEVER

In 3,045 cases, antitoxin was administered in doses ranging between 6,000 and 8,000 units. These were divided into 296 mild, 1,949 moderate and 800 severe cases. The average amount of antitoxin in the mild group was 6,870 units; in the moderate, 7,310 units; in the severe, 7,800 units. The smallest dose was 3,000 units; the largest was 20,000 units. It was administered intramuscularly.

Since the diagnosis of scarlet fever depends largely on the onset of the eruption, very few patients were

of febrile days for the mild serum treated cases was 5.15, while for the nonserum group it was 6.82; for the moderate serum treated it was 5.74 and for the nonserum group 7.08; for the severe serum treated it was 6.92 and for the nonserum group 8.80.

EFFECT ON THE INCIDENCE OF COMPLICATIONS

It was definitely noted that the incidence of complications was less in the group of serum treated patients (table 2). The total percentage of complications in the 3,045 serum treated was 18.85, in contrast to 26.13 per cent for the 2,332 nonserum treated. The most

admitted within the first twenty-four hours of their illness. Consequently the majority of patients received antitoxin from forty-eight to ninety-six hours after the onset of the disease. Therefore it must be noted that the day on which antitoxin was given corresponds to the day of admission to the hospital. The number of patients who did not receive antitoxin was 2,332; of this number there were 866 mild, 1,209 moderate and 257 severe cases.

TABLE 2.—Percentage of Complications: Comparison of Complication Incidence in Serum and Nonserum Groups—Totals for Three Years

	3,045 Serum		2,332 No Serum	
	Cases	Per Cent	Cases	Per Cent
Otitis media.....	225	7.39	229	0.83

Total percentage.....	575	18.85	610	26.13

It can be seen (table 1) that antitoxin shortens the febrile stage of the disease, irrespective of the severity. Except for the patients who received antitoxin within the first twenty-four hours of their disease, there was noted a definite decline in the temperature and a reduction in the febrile days ranging from 0.02 day to 2.71 days. The later the administration of antitoxin in relation to the day of disease, the longer the duration of fever. The reason for the failure of those cases in which antitoxin was given in the first twenty-four hours to follow the general rule is not clear in our minds. Although the reduction of the febrile days is not outstanding in the mild and moderate serum treated cases, it is nevertheless impressive in the severe group. Here the reduction ranged from 1.16 to 2.37 days and was more constantly observed. The average number

striking decrease in the number of complications was noted in otitis media, adenitis and arthritis groups, which incidentally accounted for 75 per cent of the total number of complications. It may be seen that there is very little difference in the incidence of nephritis and bronchopneumonia in the two groups.

A study of the incidence of complications in relation to the severity of the disease (table 3) shows even more definitely the part played by antitoxin in this respect. As every one suspects, the incidence of complications is in direct proportion to the severity of the disease. In the mild serum treated group the incidence of complications was 11.13 per cent, in comparison to 18.51 per cent in the nonserum treated; moderate serum treated 17.74 per cent and nonserum treated 27.58 per

TABLE 3.—Percentage of Complications in Each Group

	Mild Percentage of Complications in		Moderate Percentage of Complications in		Severe Percentage of Complications in	
	296 Cases With Serum	866 Cases Without Serum	1,949 Cases With Serum	1,209 Cases Without Serum	800 Cases With Serum	257 Cases Without Serum
Otitis media.....	5.07	6.70	6.73	10.42	9.99	18.23
Mastoiditis.....	0.67	1.39	0.87	0.57	1.00	3.50

cent; severe serum treated 26 per cent, and nonserum treated 52.79 per cent. Thus it is observed that the influence of antitoxin in the incidence of complications becomes more striking in the more severe forms of the disease.

The death rate in the 3,045 cases in which antitoxin was given was 0.85 per cent (twenty-six), while in the 2,332 cases in which serum was not given the death rate was 0.43 per cent (ten). A greater death rate in

the group in which serum was given may be explained by the treatment of a larger number of more critically ill patients in this group, 30 per cent of whom died within twenty-four hours after admission to this hospital. There were no deaths from anaphylaxis.

SERUM DISEASE

The high frequency of fairly severe serum reactions that followed the use of scarlet fever antitoxin in the early days of its inception is perhaps the chief reason why it is not in more general use today. Investigators report the incidence of serum disease at figures varying from 15 per cent in Doolittle's⁸ series to nearly 100 per cent in Bagley's⁹ experience. Undoubtedly the high incidence and severity of serum disease reported by some investigators is partly due to the insufficient refinement and concentration of the early serums. This was definitely the case at the Philadelphia Hospital for Contagious Diseases. Antitoxin purchased from different manufacturers varied greatly as to concentration, and therefore a greater number of serum reactions occurred in those who received serum of low concentration. Today, this has been practically eliminated.

In our study, 36.3 per cent of 1,106 patients had serum disease (table 4). A few of these reactions were immediate, but most of them were manifested by delayed urticarial lesions accompanied by moderate

TABLE 4.—Incidence of Serum Reactions

fever, generalized adenopathy and arthralgia, which tended to make the patient uncomfortable for three or four days. Less common features were morbilliform or scarlatiniform eruptions, mild or severe febrile reactions.

From time to time it has been attempted to decrease the number and severity of these uncomfortable conditions through the aid of certain drugs. Some of the patients in this series received ephedrine salts in doses of from one-eighth to 1 grain (0.008 to 0.065 Gm.) daily for seven days; others were given one or more capsules containing a similar dose of ephedrine plus calcium. Ephedrine was given to 1,028 patients. In this group the incidence of serum disease was 33 per cent. Ephedrine and calcium was given to 358 patients. In this group the incidence of serum disease was 34.5 per cent, while serum disease occurred in 38.8 per cent of the 1,659 patients who did not receive any drugs.

SUMMARY

1. Of 5,377 cases of scarlet fever studied, scarlet fever antitoxin was administered in 3,045 and was not administered in 2,332.

2. In a comparison of the serum with the nonserum treated cases, a slight decrease in the number of febrile days in the mild and moderate groups was noted, and a substantial reduction in the severe group.

3. The incidence of complications was definitely less in the serum treated cases in comparison with those not so treated. This effect was most prominent in the severe group.

4. Serum reactions occurred in 36.3 per cent of the patients treated with antitoxin. The use of ephedrine compounds had a slight effect on the prevention of serum disease.

CONCLUSION

Antitoxin is indicated in the moderate and severe forms of scarlet fever.

Front and Luzerne streets.

THE SECONDARY CASE OF SCARLET FEVER

ARCHIBALD L. HOYNE, M.D.

AND

JOHN HAYS BAILEY, PH.D.

CHICAGO

During the year 1932 certain changes made in the scarlet fever quarantine requirements by the Illinois State Department of Health and the Chicago Board of Health offered an unusual opportunity for a study of the secondary case of scarlet fever and the duration of scarlet fever infectivity. Four series were investigated, in which 4,315 patients were discharged from the Municipal Contagious Disease Hospital under different regulations.

In the first group the quarantine period was four weeks for uncomplicated cases. Patients with abnormal discharges, however, were held in the hospital until they were clinically well, with the stipulation that the maximum period should not exceed ninety days. Under this arrangement, between Jan. 1 and July 6, 1932, there were discharged 1,454 patients, 235 of whom were adults. Among the 1,454 patients, sixty-two, or 4.2 per cent, were responsible for secondary or so-called return cases of scarlet fever. To these sixty-two patients, eighty-two new cases of scarlet fever could be directly traced. The latter number were admitted to the hospital. How many more secondary cases may have occurred is not known, for obviously additional ones may have entered other contagious disease hospitals or have been cared for in their own homes. Adults made up 9.7 per cent of the sixty-two patients responsible for infecting others. This in effect contradicts the inference of Gordon¹ that adults are not an important factor as foci for secondary cases of scarlet fever.

Of the sixty-two patients responsible for secondary cases there were but seven who had had complications of a suppurative nature. On the other hand, the remainder (fifty-five) had at no time suffered from abnormal discharges, although sixteen of these did have either cervical adenitis, nephritis or other nonsuppurative conditions. The remaining thirty-nine (62 per cent) had experienced no complications whatever. Expressed in percentage, it is evident that only .11 per cent of the secondary cases were due to released patients who had suffered from septic processes (chart 1). Thus it is apparent that the very type of released patient that one might regard with the greatest fear from an infec-

8. Doolittle, S. E.: Northwest Med. 26: 26 (Jan.) 1927.

9. Bagley, H. E.: J. Michigan M. Soc. 26: 48 (March) 1927.

tive standpoint was in reality the least dangerous. Although 342 of the total patients discharged had had complications of a suppurative nature, there were but seven of these who transmitted scarlet fever following their release.

The eighty-two secondary cases of scarlet fever mentioned may be divided as follows: fifty, or 61 per cent, could be traced to thirty-nine uncomplicated cases; twenty-one, or 25.7 per cent, were linked to primary cases which had had cervical adenitis or other nonsuppurative conditions, while the remaining eleven, or 13.3 per cent, were the only ones traceable to primary cases that had experienced any septic process. This demonstrates that the patient who has had uncomplicated scarlet fever is no less likely to transmit infection to others than the patient who has suffered from suppurative processes during the acute attack.

Among the eighty-two secondary cases described, it is interesting to note that suppurative processes developed in 23 per cent, while septic complications had occurred in only 11 per cent of the primary cases. In other words, the rate of suppurative complications among the secondary cases was more than 100 per cent greater than among the primary cases. This indicated that the virulence of the organism is likely to be increased by passage from one sibling to another.

The quarantine regulations in group 2 provided that all uncomplicated cases of scarlet fever be released from the hospital at the end of three weeks. If there were complications, however, it was necessary that the patient be held until clinically well or until two cultures on blood agar from any abnormal discharges taken one week apart were negative. With these quarantine regulations in force, 500 scarlet fever patients were released during the period between July 7 and Nov. 28, 1932. All but thirty-eight were children. Among the total it was definitely established that thirty-five individuals

cent contributed 56 per cent of the secondary cases in this group.

Of the fifty-nine secondary cases, suppurative processes developed in fourteen, or 23 per cent. On the other hand, only 17 per cent of the released patients responsible for secondary cases had had suppurative conditions. As in the preceding group, it is shown that the number of suppurative cases is greater among the

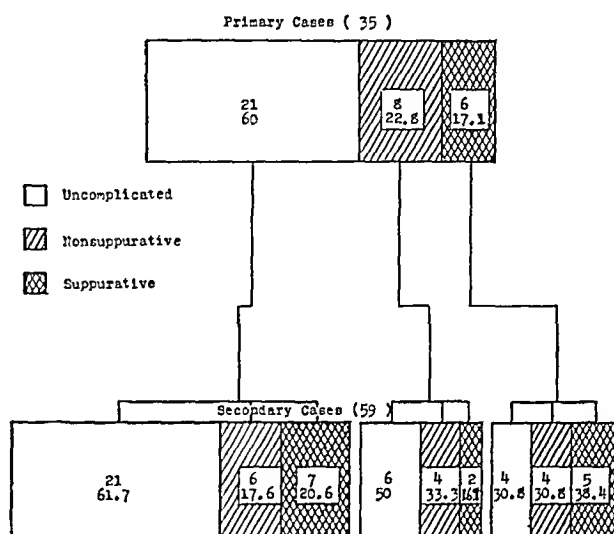

Chart 2.—Three weeks quarantine period without culture.

secondary infections than among the primary infections. Furthermore, in contrast to the 56 per cent of the secondary cases that were traceable to released patients who had suffered from no complications, only 22 per cent were attributable to patients with suppurative complications. Expressed in terms of percentage, this means that the occurrence of suppurative complications was more than 50 per cent greater in the secondary cases than in the primary ones (chart 2).

In the 500 releases of group 2, only 7 per cent were adults and all the secondary cases arose from children. Here we call attention to the fact that scarlet fever patients released from the hospital as recovered transmitted the disease to others during the warm months of the year, notably July, August and September. Moreover, though most of the patients in the group were released during the warm season, the infectivity rate was at its peak (7 per cent) and the secondary rate was likewise at its height (11.8 per cent). This diametrically opposes the opinion of Gordon,¹ who states that "the secondary case rate [of scarlet fever] is materially lower" during the summer months.

Group 3 was made up of patients who were released under quarantine regulations which stipulated that a negative nose and throat culture on blood agar be secured in every uncomplicated case before dismissal, regardless of the prolongation of hospitalization. Three weeks, however, was the minimum quarantine period. In complicated cases the rules were the same as set forth for group 2. With the foregoing requirements in force there were 272 patients, twenty-four of whom were adults, released from the hospital between Nov. 29

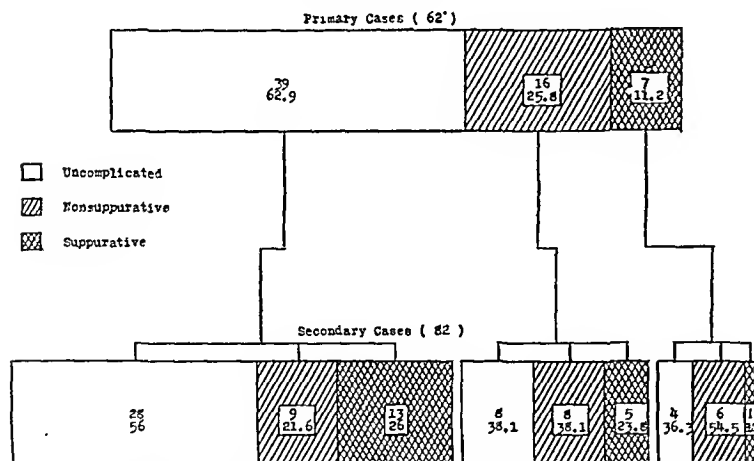

Chart 1.—Four weeks quarantine period. In the charts the upper figure gives the number of cases in each group, the lower figure the percentage.

(7 per cent) were the cause of fifty-nine secondary cases of scarlet fever, nor does this take into consideration, as pointed out in regard to group 1, the possibility of other secondary cases that did not enter the hospital and were thus unknown to us.

Among these thirty-five primary cases, only six had presented suppurative processes, whereas twenty-one were entirely free from complications. Again we were impressed with the fact that 60 per cent of the primary cases had presented no complications, yet this 60 per

and Dec. 24, 1932. In this small group, but eight were shown to have infected others following their release, resulting in a total of nine secondary cases, or slightly more than a ratio of 1 per primary patient, whereas in groups 1 and 2 the ratio was nearer 2 to 1.

While this group concerns only 272 patients, we nevertheless believe that it is of interest in connection with the quarantine problem as it pertains to scarlet fever. Under this plan there were less than 3 per cent known to have transmitted scarlet fever following release. Among these eight, however, it was again disclosed that the complicated case was not a greater source of danger than the uncomplicated, for these two classes of patients were equally divided. In this particular group, four uncomplicated cases were responsible for four secondary cases, two of which showed complications of a suppurative nature, whereas the other four were responsible for transmitting scarlet fever to five patients, three of whom developed complications. While this ratio differs slightly from that shown in the previous groups, we believe it may be explained on the basis of the small number of released patients (chart 3).

In group 4 the quarantine requirements specified that all uncomplicated cases of scarlet fever were eligible for release at the end of three weeks, provided a negative nose and throat culture on blood agar be secured before dismissal. This culture was taken as a routine procedure on the nineteenth day. If such a culture was positive, the patient with no complications was then held in quarantine for an additional week, being released at the end of twenty-eight days without further effort

whom were adults. Eighty-five, or 4 per cent, of the discharged patients were responsible for 132 secondary cases of scarlet fever. In view of the opinion sometimes expressed, which has been previously referred to, it is interesting to note that 9.4 per cent of the eighty-five known vectors were adults. This again emphasizes the part the adult may play in the transmission of scarlet fever.

Chart 4.—Released after three weeks if culture was negative; if not, after four weeks.

We have mentioned that, under the arrangement applied in group 4, eighty-five of the 2,089 patients dismissed from the hospital were sources of infection in which 132 known cases of scarlet fever developed. Of the eighty-five patients there were but twenty-six (31 per cent) who had suffered from suppurative processes, while forty-one, or 48 per cent, did not have any complications. These gave rise, however, to seventy of the secondary cases (53 per cent), while the twenty-six patients (31 per cent) who had experienced suppurative complications were responsible for only thirty-seven of the secondary cases (28 per cent) in this group. The remaining eighteen suffered from such conditions as

TABLE 1.—Summary of Observations

	Adults	Children
Number of patients discharged.....	620	3,695
Number of patients transmitting scarlet fever.....	14	176
Infectivity rate.....	2.27%	4.76%
Number of secondary cases.....	26	256
Secondary case rate.....	4.1%	6.9%

cervical adenitis or other nonsuppurative conditions (chart 4).

Therefore, fifty-nine of the total eighty-five patients in this group who served as foci of infection had experienced no complications of a suppurative nature. This again demonstrates the fallacy of believing that it is only the scarlet fever patient who has suffered from abnormal discharges that is likely to transmit scarlet fever to others following release from quarantine.

SUMMARY

1. Among 4,315 scarlet fever patients released from the hospital between Jan. 1, 1932, and July 6, 1933, there were 190 known vectors responsible for secondary cases of scarlet fever. Undoubtedly there were many other instances not disclosed by our investigation.

2. Of the 4,315 scarlet fever patients released, 620, or 14 per cent, were adults and fourteen of these were known vectors (tables 1 and 2).

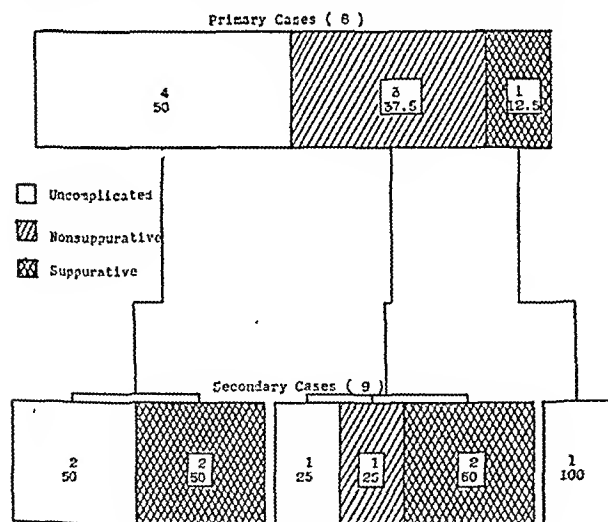

Chart 3.—Released only on negative culture.

to determine by means of cultural methods whether or not he continued to harbor hemolytic streptococci.

If the patient suffered from a complication, he was held, as in the preceding group, until he was clinically well or until two successive negative cultures were secured from any abnormal discharges. These cultures were taken on blood agar plates at weekly intervals. In this group there were released between Dec. 25, 1932, and July 6, 1933, 2,089 scarlet fever patients, 323 of

3. Of the 190 known vectors, 150 (79 per cent) were nonsuppurative, whereas but forty (21 per cent) had suffered from suppurative processes.

4. The 190 known vectors were responsible for 282 secondary cases.

5. Fourteen per cent of the total releases were adults and 7 per cent of the 190 known vectors were adults. One out of every forty-four adults at the termination of quarantine transmitted scarlet fever to a susceptible. With children, one out of every twenty-nine under similar circumstances was responsible for secondary cases.

CONCLUSIONS

1. We have demonstrated that the patient who has had uncomplicated scarlet fever, contrary to the opinion often expressed, may be as dangerous to the community following release from quarantine as the patient who has suffered from abnormal discharges during the acute attack.

2. On the basis of our data we believe that the adult patient who has suffered from scarlet fever cannot be regarded as a negligible factor in the transmission of the disease following his release from quarantine.

TABLE 2.—Cases According to Groups

	Total Trans- Number mitting of Scarlet Patients Fever Dis- After charged Release From From Hospital Hospital	Number of Cases Infec- tivity Rate, per Cent	Number of Secon- dary Cases	Secon- dary Case Rate, per Cent	
Group 1: Four weeks quarantine period	1,454	62	4.26	82	3.6
Group 2: Three weeks quarantine period	500	35	7.00	59	11.8
Group 3: Quarantined until nose and throat cultures were nega- tive	272	8	2.94	9	3.3
Group 4: Three weeks quarantine period if nose and throat cul- tures were negative, otherwise four weeks	2,069	85	4.07	132	6.3

3. The number of secondary (return) cases of scarlet fever bears an inverse ratio to the length of the quarantine period and is not dependent on seasons.

4. The secondary case of scarlet fever contracted from one of a mild type is frequently characterized by unusual severity. The converse is also true.

5. It is our opinion that the spread of scarlet fever cannot be effectively controlled by the methods of quarantine now in general use. The morbidity and mortality of scarlet fever, as well as that of diphtheria, can never be reduced to a satisfactory level without resorting to thorough and systematic methods of active immunization.

3026 South California Avenue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. LUCCHESI AND BOWMAN AND
DRs. HOYNE AND BAILEY

DR. JOHN A. TOOMEY, Cleveland: Drs. Lucchesi and Bowman advocate the use of antitoxin because their treated patients did not have fever as long as the untreated and the complications were less in the former group. They compare 3,045 patients who were given antitoxin with 2,332 who were not. The numerical difference between these two groups of cases is 713, or nearly 24 per cent, a differential that would have to be considered in the interpretation of their results. As far as the number of days of duration of fever is concerned,

correction for such a differential would tend nearly to equalize the averages, thus robbing these statistics of some of their importance. One could hardly compare 257 nontreated with 800 treated severely ill patients and be justified in concluding that because the former had a complication rate of 52.79 per cent and the latter a complication rate of 26 per cent, scarlet fever antitoxin should therefore be used. If one is warranted in these conclusions, one must also logically conclude that, if there were more severely ill patients in the nontreated group, the complication rate would be greater or at least remain the same; but everybody knows that the more cases there are, the lower is the complication rate. I noticed that the authors recommended the early use of antitoxin, and yet I got the impression from their charts that the later they treated the patient the better were the results. The authors state that the reduction in fever after the injection of antitoxin is not outstanding in the mild or moderately ill group of scarlet fever patients. If this is so and since the authors aver that serum reactions tend to make the patient uncomfortable for at least three or four additional days, one wonders why it should be used in the milder cases. I have used antitoxin in treating the severely ill and toxic type of scarlet fever patient but have never been quite sure that it did much good. Drs. Hoyne and Bailey present statistics on the effect of various methods of quarantine on the number of scarlet fever cases that arise secondary to cases discharged from the hospital. The lowest infectivity rate was found in the group of uncomplicated cases isolated at least twenty-one days and whose cultures were negative before discharge from the hospital. In cases of the same group that showed complications, two negative cultures were obtained a week apart on blood agar medium. The infectivity rate here was 2.94 per cent and the secondary case rate for this group was 3.3 per cent. A striking point made by the authors is the fact that the majority of secondary cases arose not from patients who were discharged from the hospital with suppurative or open lesions but from those who had no complications whatever, thus demonstrating that the uncomplicated case of scarlet fever is often more likely to give rise to secondary cases than the complicated one. If this is true, it must follow that present criteria of infection and isolation are totally inadequate. I agree that the ultimate answer to the quarantine question lies in prophylactic immunization against the disease, but I think that much experimentation will have to be done before an immunization product is available the use of which can be pushed as a general public health measure. I doubt whether the mortality rate of the present mild type of scarlet fever will be much affected by any method of immunization.

DR. J. E. GORDON, Detroit: Drs. Hoyne and Bailey are to be thanked for emphasizing that patients convalescing from simple uncomplicated scarlet fever not infrequently transmit the disease. This often fails to receive the consideration it warrants. However, if one considers the kind of patient most likely to communicate scarlet fever to another person, that is another problem. Infecting cases have been distributed into three groups: those in which the course was uncomplicated, those with nonsuppurative complications and those with suppurative complications. Most of the infecting cases were in the group without complications, but so are most of the cases of scarlet fever. The essential problem is which of the three groups is relatively most likely to communicate scarlet fever infection and which requires the greatest precautions for adequate control of the disease. There are differences in the proportion of patients who tend to transmit the disease, dependent on the number and nature of the complications they have had. Not all active suppurative conditions are of equal danger. Patients who have had suppurative otitis media transmit the infection with about the same frequency as do those who did not have complications. Of course, they are restricted for longer periods of time. By contrast, I have found that patients with cervical adenitis and those with nasal or sinus infections constitute the most important problem. Dr. Toomey nicely emphasized the diagnostic difficulties associated with complications related to the nose. Drs. Hoyne and Bailey have reported a summer in which infecting cases were particularly frequent. Data over six consecutive years in Detroit have shown that the rate is generally lowest at that time. In one of the six years we had an increased rate during the summer, and most interest-

ingly that was followed by a greater prevalence of scarlet fever the next year, which duplicates the quoted experience. At present we are employing in Detroit an isolation period of two weeks for adults and three weeks for children. The infecting case rate is essentially the same as that reported here for the four weeks period; this year, about 4 per cent; the average for the three years it has been practiced, a bit less. Drs. Hoyne and Bailey stated in their conclusion that no known isolation plan suffices to control scarlet fever adequately. It would seem logical, then, to employ the shortest period that would give satisfactory results. Judged by the frequency of infecting cases, essentially as good results have been obtained in Detroit with these shorter periods as with the longer isolation for four weeks.

DR. P. F. LUCCHESI, Philadelphia: I must disagree with Dr. Toomey on several conclusions. He believes that the difference of 713, or 24 per cent, between the 3,045 patients who received serum and the 2,332 who did not, should not give our report a great deal of value. By the same token, he believes that 257 severe cases not treated with serum, with complications of 52.9 per cent, in comparison with the 800 serum treated cases of the severe type with a complication rate of 26 per cent, should likewise receive very little importance. If I may borrow Dr. Toomey's own method of conclusion, it would seem that if we increased the number, the small group of nonserum treated severe cases to 800, this would not account for the difference of twice the number of complications in the serum treated cases. There was a consistency in the lessening of the incidence of complications in the three groups. We performed a skin test in order to avoid anaphylactic shock and not to predict a serum disease. I have seen several patients, however, in whom the skin test was negative but who were definitely positive or sensitive to the serum. At present we are not getting the same high incidence of serum disease that we got in the early days of antitoxin. This undoubtedly is caused by the more refined antitoxin used at present. I agree with Dr. Toomey that ephedrine or ephedrine and calcium salts have little effect in the incidence and prevention of serum disease. Dr. Toomey stated that he had the impression that we obtained better results in those cases in which the antitoxin was given later. We did not mean to create that impression. In the light of our present experiences I believe that Dr. Bowman and I are justified in concluding that scarlet fever antitoxin will be of value if used in the moderately or severely toxic cases. Dr. Gordon said something in favor of a two weeks quarantine period for adults and three weeks for children. In Philadelphia we practice the minimum of a thirty-day quarantine period, provided they have no suppurative complications. Our proportion of return cases is seldom over 3 per cent, and I think the reason for this is the keeping of our cases in the hospital for an average of thirty days. Last year, with more than 3,000 cases treated, the hospitalization averaged thirty-three days.

DR. ARCHIBALD L. HOYNE, Chicago: It is true, as Dr. Toomey infers, that in scarlet fever cases classed as uncomplicated there may actually be some complication not ordinarily disclosed by the customary examination made at the time of the patient's release. However, we do not feel justified in requiring that all scarlet fever patients undergo a roentgen examination in order to determine whether or not they may have an infected sinus. There seems to be no doubt that virulence is increased by rapid transmission of a disease from one patient to another. That probably explains why so many of the secondary cases are severe, although the disease is acquired from a mild case. This brings up the question as to what is meant by the term "mild." My understanding is not the same, apparently, as of many others. Frequently, if there is not a high death rate the scarlet fever is referred to as mild. The fact that the death rate is not high does not necessarily mean that the disease has been mild. The question of the secondary case of scarlet fever is in itself complicated and, in discussing it, it is difficult to tell what is meant. I feel that Dr. Gordon is in error in believing that we did not properly calculate what we intended to demonstrate. We did not attempt to draw any conclusions as to the infectivity rate of any particular class of patients. The infectivity rates that we showed here are based on the total number of patients discharged. The infectivity rate in no way referred to either the complicated or the uncomplicated cases as separate groups. It had to do merely

with all the patients who transmitted the disease. Therefore, I still think that what we undertook to show we did show and that it is essentially correct. When quarantine is being discussed, there are different systems of figuring its duration. My belief is that, because of the difference in establishing the quarantine time, the minimum quarantine period in Chicago at present is less than the minimum period in Detroit.

ATYPICAL FLEXNER DYSENTERY

A PRELIMINARY REPORT OF THE JERSEY CITY EPIDEMIC

JOSEPH FELSEN, M.D.

NEW YORK

EMILIE V. RUNDLETT, M.D.

JAMES SULLIVAN, M.D.

AND

HAROLD GORENBERG, M.D.

JERSEY CITY, N. J.

The Jersey City outbreak is a repetition of incidents known with regard to bacillary dysentery since Shiga first described the causative organism in 1898 in Japan, and Flexner in 1899 in the Philippines. The outbreaks in the United States have been due almost entirely to the acid-producing type represented by the Flexner Y and Sonne strains. Though serologically and bacteriologically distinct, these organisms have many characteristics in common. The paradysentery strains of Castellani and similar organisms described by other investigators probably belong to this group and illustrate the heterogeneous nature of the dysentery bacillus. Nelson considers Castellani's paradysentery identical with Sonne dysentery. One of us (J. F.) recently described an outbreak of the latter disease in New York City, which was terminated a few months before the inception of the Jersey City epidemic. The similarity of the clinical, bacteriologic and immunologic features in these two outbreaks was so marked that they will be again referred to in this communication.

Widespread epidemics of bacillary dysentery have occurred in Europe and elsewhere since 1538. They have been encountered among the armies of almost every nation from the Crimean to the World War. These epidemics were based on well recognized hygienic and sanitary factors incident to warfare. Outbreaks in civilian life, however, in communities with presumed sanitary facilities, have also been common. The "asylum dysenteries" of England, the Flexner Y type of "summer diarrheas" in infants, the milk-borne and water-borne outbreaks in this country and abroad emphasize the belief that the disease is always endemic and that periodic outbreaks occur, often without any apparent laxity in sanitary regulations.

EPIDEMIOLOGY

The Jersey City outbreak began about July 21, when five children were stricken with dysentery. The early cases appeared in one quarter of the city, but others soon occurred elsewhere and by August 10 there were 184 reported cases. It was evident that the entire outbreak represented a contact infection, and further investigation revealed the fact that Flexner dysentery had been endemic in Jersey City for about one year. This was ascertained by referring to the clinical and laboratory records at the Medical Center. It appeared quite certain that sporadic cases kept the disease going, many

of the milder cases probably having been unrecognized until enough susceptible contacts occurred to cause an outbreak. Many of the very early cases occurred in families. Thus, on July 23 five members in one family were involved with one death, a child aged 7. July 30, three members in a family were affected with one death, an infant aged 21 months. This was a prominent feature of the subsequent cases, in one instance all members of a family being confined to the Isolation Hospital at the Medical Center.

Of the total number involved up to the present, approximately 100 patients have been studied at the Medical Center. It is our impression that the true extent of the outbreak will never be accurately known, because many of the patients are not sick enough to seek medical attention. The same appears to be true for the surrounding communities. Only a careful cultural and serologic check up on an extensive scale will furnish accurate information in this regard. On August 10 one of us (J. F.) definitely diagnosed a case in New York City in a boy, aged 6, who had returned from the Catskills a few days before. He had been playing with two neighbor children, who were confined to bed with bloody diarrhea. Serologic and cultural studies were positive for the Flexner organism, as were cross studies against our Jersey City strains and serums. The one point we wish to stress from the epidemiologic standpoint is the importance of detecting the symptomless or mild cases. Cultures should be made on all contacts and the serum tested for the agglutination titer. Intramural hospital infections are common and may be avoided by isolating every newly admitted child and every adult with loose bowel movements, for forty-eight hours, until the presumptive tests have proved negative. This can be effectively carried out by making a culture

played by the healthy carrier. Shiga, moreover, states that the carrier is the chief factor in the spread of the disease. In Japan, where the more toxic type of dysentery (Shiga) is prevalent, the disease is said to persist in the interepidemic period through the medium of healthy carriers, mild sporadic cases and convalescents. The rôle of domestic animals and flies is now being studied with the cooperation of Health Commissioner

Summary of Age and Familial Incidence and Symptomatology
(100 Patients)*

Age Groups:	
Infants	15%
Adults	15%
Children	70%
Familial Incidence:	
Two in family.....	3
Three in family.....	2
Four in family.....	4
Six in family.....	1
Symptomatology:	
Vomiting	27%
Bloody and mucoid diarrhea.....	90%
Colic	50%
Prodromal symptoms: anorexia, lassitude.....	10%
No diarrhea	5%
Constipation following diarrhea.....	40%
Neurotropic:	
Herpes	13%
Convulsions	4%
Stupor	5%
Rigidity of neck.....	13%
Positive Kernig and Brudzinski signs.....	10%
Ankle clonus	2%
Positive Babinski	2%
Disease Types:	
Typical Mild.....	63%
Severe	35% to 20%
Neurotropic	13%
Appendicular	3%
Afebrile, asymptomatic	4%

* These figures are subject to slight inaccuracy owing to borderline cases. Some of the neurotropic group also fell in the severe type.

Jersey City outbreak of atypical Flexner bacillary dysentery. Total figures include only the reported cases. Note rapid increase in incidence after the first ten days. Thirty-two cases reported in the first eleven days, 156 in the second eleven day period.

of the fresh stool on an Endo plate and setting up the suspected colonies against known immune serums. The patient's serum agglutination titer can be determined on the same day, but the results may be negative until the fifth or sixth day. The work of Conradi,¹ Wollstein,² Duval and Shorrer³ indicates the important rôle

Salmon and the local Society for Prevention of Cruelty to Animals. It is known that dogs may contract dysentery, and we are now examining the diarrheal droppings on the streets of Jersey City. One of our patients had a sick cat for one week prior to the onset of his illness. Kruse and Bowman⁴ have reported Flexner dysentery in monkeys, and Messerschmidt⁵ has recovered the same organism from healthy rabbits. The dysentery organism persists for long periods in the soil, as illustrated by the outbreak at the Chalons military camp in 1889⁶ when troops occupying a site over an old latrine used by dysenteric soldiers the year previously contracted the disease.

Isolation of patients, careful handling of food and water supplies, thorough examination of all food handlers, adequate screening against flies and instruction in personal hygiene are necessary measures in controlling the spread of the disease. Hospital outbreaks have been reported in this country and abroad involving the Sonne as well as the Flexner organisms.⁷

CLINICAL ASPECTS

The statistical data concerning the hospitalized patients, nearly all of whom were at the Medical Center, are summarized in the accompanying table.

The majority of cases occurred in children, usually from the poorer quarter of the city. It is surprising,

1. Conradi: Festschrift für Robert Koch, Jena, 1903.
2. Wollstein, Martha: Studies from the Rockefeller Institute of Medical Research 2, 1904.
3. Duval, C. W., and Shorrer, E. H.: Studies from the Rockefeller Institute of Medical Research 2, 1904.

4. Kruse and Bowman, cited by Castellani, Aldo, and Chalmers, A. J.: Manual of Tropical Medicine, New York, William Wood & Co., 1920.
5. Messerschmidt, cited by Lentz: Ztschr. f. Hyg. 41, 1902.
6. Zinsser, Hans: Textbook of Bacteriology, New York, D. Appleton & Co., 1922, p. 715.
7. For general literature covering this subject see Felsen, Joseph, and Ososky, A. G.: Sonne Dysentery, J. A. M. A. 103:966 (Sept. 29) 1934. Felsen, Joseph: Am. J. Digest. Dis. 1:297 (July) 1934.

however, to note the relatively large number of adults affected.

Typical, Mild Form.—The typical case was of the mild type. The incubation period was short, often only a few hours. There were no prodromal symptoms other than anorexia or slight lassitude. The onset was generally quite sudden with colic and profuse watery diarrhea, often greenish and foul, with bright red specks or fluid blood and mucus appearing after from twenty-four to forty-eight hours. In some cases there was vomiting, usually ascribed to "food poisoning." There was only a moderate pyrexia with a corresponding increase in pulse rate. The average patient looked very well and complained little or not at all. Often the patient would be brought to the hospital on the third or fourth day of illness and in a day or two the temperature would be normal. Very shortly thereafter, usually the same or the next day, the diarrhea ceased. In some of the positive cases the bowels were actually constipated after admission. At or about the sixth day the patients often clamored to be sent home and would have been were it not for the bacteriologic check up. Sigmoidoscopic examinations were made in a limited number of cases and revealed a reddened mucosa weeping bloody fluid and covered in patches with thick, yellowish gray mucus. Ulceration, when present, was very superficial and could be made out only by careful examination of the reddened, moist mucosa. Follicular hyperplasia was nearly always present and was noted as multiple small punctate elevations of the mucosa due to hyperplasia of the underlying solitary lymph nodules. It is interesting to note that some patients exhibited definite inguinal lymphadenopathy due to inflammation extending to the anorectal margin. Lymphatic drainage from this area is to the inguinal region. We include in this group a member of the intern staff who was handling the hospitalized patients and who had a brief attack of bloody diarrhea unaccompanied by any marked constitutional symptoms.

The mild form of the disease as encountered by us may be described as an acute inflammatory condition of the intestine, characterized by a bloody and mucoid diarrhea accompanied by colic, having a brief incubation period, of short duration and of a relatively nontoxic type. This definition coincides with that given by one of us for an identical clinical picture seen in Sonne dysentery.

Severe Type.—In some of the infants and younger children a severe form of the disease was encountered. The onset was sudden with headache, vomiting, colic, profuse bloody diarrhea and prostration. By the time the patients reached the hospital they were markedly dehydrated, acidotic and acutely ill. It is quite certain that some of the infants were saved only by the prompt hypodermoclyses and phlebotomies administered by the intern staff. In this form the pyrexia was often as high as from 104 to 105 F., and the duration of the disease was prolonged beyond the usual six day period. It may be noted in passing that some of the severe cases occurred in adults. Thus far the mortality in the severe type of the disease has been 2 per cent. We have not encountered any cases of sudden death as described by Harvey⁸ and by Charles and Warren.⁹ It is noteworthy that in the severe form there was an initial

leukopenia with gradual return to normal or even a leukocytosis during convalescence.

Unusual Types; Neurotropic Type.—Some of our patients exhibited labial herpes and meningitic symptoms such as severe headache, violent emesis, convulsions, drowsiness or stupor. These were not infrequently accompanied by rigidity of the neck and positive Kernig and Brudzinski signs. These patients appeared to fall into a definite group. While herpes is generally conceded to be a virus infection, we were impressed by the constant association of this lesion with meningitic symptoms. The spinal fluid, however, was negative and the symptoms subsided after a few days. Several of these cases were admitted with a tentative diagnosis of meningitis. It is possible that this form of Flexner dysentery is caused by a neurotropic strain.

Appendicular Type.—Some of our cases were admitted with a diagnosis of acute appendicitis and, after observation, were transferred to the Isolation Hospital. The suggestive symptomatology is due to the mesenteric adenitis and lymphoid hyperplasia, which is often most marked in the ileocecal region. Nelson,¹⁰ Clayton¹¹ and Felsen have described similar cases. These patients are apt to have a normal leukocyte count or actual leukopenia early in the disease.

Afebrile Type.—Some of our patients have been completely afebrile throughout their stay in the hospital, though bloody and mucoid diarrhea was present. These patients generally exhibit no noteworthy constitutional symptoms.

Asymptomatic Type.—A few adults and children have entered the hospital because of one or a few loose bowel movements without blood or mucus. Many of these cases undoubtedly exist as they have in other epidemics and medical attention is sought only because of the publicity incident to an outbreak.

CULTURAL, IMMUNOLOGIC AND ANIMAL STUDIES

We are studying many of the strains isolated thus far and the immunologic titers of the serums during the disease and convalescence stages. Discharged patients and contacts are now being recalled for further investigation. We have reproduced the disease in rabbits by intravenous inoculation of the Jersey City strains and recovered the organism in the feces. Toxin studies, serum and bacteriophage therapy and widespread vaccination of children are being initiated.

POSTMORTEM REPORT

One infant exhibited a general lymphoid hyperplasia of the small and large bowel, notably the ileum and ileocecal region. Peyer's patches and solitary lymph nodules stood out prominently. After fixation, the latter showed a peculiar central dimpling suggestive of early necrosis. There was a generalized mesenteric lymph node hyperplasia, which appeared to be most marked at the ileocecal angle and on the posterior aspect of the cecum. There were numerous superficial ulcerations of the mucosa with vascular congestion. Sections of the spleen revealed hyperplastic splenic lymph nodules surrounded by a prominent hemorrhagic halo containing many macrophages loaded with blood pigment. In places the connective tissue trabeculae were similarly outlined.

THERAPY

Flexner dysentery as we have encountered it is a self limited disease. Most of the patients received repeated doses of castor oil in order to favor elimination of the toxin, which is known to be excreted through the wall into the bowel lumen. In dehydrated cases, liberal phlebotomies and hypodermoclyses were given. Aside from these measures the treatment was essentially symptomatic. It is too early to report on the effects of specific therapy, as many of the patients enter the hospital on or about the third or fourth day of the disease and often are well in one or two days.

A NEW DANGER IN DINITROPHENOL THERAPY

AGRANULOCYTOSIS WITH FATAL OUTCOME

SOLOMON SILVER, M.D.

NEW YORK

With the use of alpha-dinitrophenol reaching proportions that must astound and alarm even its enthusiastic advocates, it is felt that this report of another fatality following its administration should be published.

REPORT OF CASE

A woman, admitted to the Mount Sinai Hospital, May 26, 1934, had an irrelevant past history except for the fact that she had always been obese, averaging 250 pounds (113 Kg.). About one year previously her physician noted moderate hypertension. Two months before admission, after a careful physical examination by her physician, who found only obesity (265 pounds, or 120 Kg.) and hypertension (175 systolic, 100 diastolic), the patient was given sodium alpha-dinitrophenol in doses of one-half grain (0.03 Gm.) three times a day. This dose was gradually increased so that five weeks later the patient was taking 2 grains (0.12 Gm.) three times daily. Her weight at that time was 258 pounds (117 Kg.), a loss of 7 pounds (3.2 Kg.) since the use of the drug was begun. She then saw her physician and as he found no toxic symptoms he increased the dose of the sodium alpha-dinitrophenol to 3 grains (0.18 Gm.) three times daily, or 9 grains (0.54 Gm.) a day. It is to be noted that the largest dose taken by the patient was still within the safe limit recommended by Tainter in his publication; namely, less than 5 mg. per kilogram of body weight. This dosage was maintained for six days. At the end of this period the drug was discontinued because the patient complained of pain in the head and ears. There was no fever, excessive perspiration or skin rash. She continued to be up and about for two days after stopping the medication. The next day, four days before admission to the hospital, the patient complained of headache, fever, sore throat and progressive swelling in the right side of the neck. The next day her physician found an ulcerating lesion in the tonsillar fossae and a fever of 103.5 F. A blood count made at that time showed only 600 white blood cells per cubic millimeter. Of these, only 20 per cent were polymorphonuclear leukocytes, 10 per cent were monocytes and 70 per cent were lymphocytes. A diagnosis of agranulocytosis was made; liver extract was administered intramuscularly, and the patient was sent to the hospital, May 26.

At the hospital she was found to be very acutely ill. There was a yellow tinge to the skin (dinitrophenol), but the sclerae were not icteric. In addition to the ulcerating tonsillar lesion and the suppurating lymphadenitis below the right lower jaw, there was an infected callus of the sole of the right foot. The spleen was felt. During her hospital stay the patient's temperature varied between 104 and 105.8 F., the pulse rate between 120 and 140 beats per minute and the respiratory rate

between 20 and 42 per minute. She was treated with liver extract intramuscularly and given two direct blood transfusions of 300 cc. each on May 26 and May 28. In spite of this, her condition became worse, pneumonia developed and the patient died, May 31.

A blood culture taken two days before death revealed the presence of *Staphylococcus aureus*.

May 26, Dr. Nathan Rosenthal reported the patient's blood count as follows: hemoglobin, 94 per cent; red blood cells, 5,520,000; platelets, 290,000; leukocytes, 1,440; segmented polymorphonuclears, 4 per cent; nonsegmented polymorphonuclears, 4 per cent; lymphocytes, 92 per cent. This, he stated, was the blood picture of agranulocytosis.

May 28, Dr. Rosenthal found: hemoglobin, 95 per cent; red blood cells, 5,370,000; platelets, 250,000; leukocytes, 1,500; segmented polymorphonuclears, 8 per cent; nonsegmented polymorphonuclears, 7 per cent; eosinophils, 1 per cent; lymphocytes, 78 per cent; monocytes, 6 per cent. He stated that this blood smear showed improvement over that of May 26.

The urine showed no bile, but urobilin was present. A faint trace of albumin was the only other abnormality. The blood pressure was 125 systolic, 90 diastolic. The blood Wassermann reaction was negative. Chemical examination of the blood revealed: sugar, 200 mg.; urea nitrogen, 68 mg.; calcium, 9.8 mg., and phosphorus, 3.3 mg. per hundred cubic centimeters of blood. The icteric index was 8 and the van den Bergh reaction was negative. The bilirubin content of the blood serum was 0.3 mg. per hundred cubic centimeters.

Postmortem examination was performed under the direction of Dr. Paul Klemperer who, among the conditions present, observed bronchopneumonia of all lobes of both lungs, severe degeneration of heart, liver and kidneys, cellulitis of the right side of the neck, necrotic ulceration of the plantar surface of the left foot, and obesity. From a consideration of the clinical history the diagnosis of agranulocytosis and bacteremia were added. Smears of the bone marrow made by Dr. Rosenthal showed evidences of hyperplasia of the marrow, such as is often seen in agranulocytosis.

The report by Hoffman, Butt and Hickey¹ is the only reference in the literature to a similar reaction to dinitrophenol, but as this is, so to say, buried in a paper dealing primarily with amidopyrine, I feel that more direct attention should be called to the rôle of dinitrophenol in the production of agranulocytosis.²

Although no causal relationship can be established between the use of dinitrophenol and this patient's death from agranulocytosis, it is felt that the rapidly mounting number of toxic and fatal cases following the drug's use should greatly limit its prescription, especially since we have been unable to convince ourselves at the Mount Sinai Hospital of its efficacy in weight reduction in a carefully controlled series of twenty-four hospital and outpatient department patients. These cases convinced us that dinitrophenol was of use only when combined with dietary restriction and that dietary restriction had to be continued after the therapy with the nitrated phenol had been stopped. In view of this and the fact that we are treating a relatively benign condition with a substance of undetermined toxicity, we have, for the present at least, discontinued the use of dinitrophenol in the hospital and recommend strongly that it be made available only on a physician's prescription.

Addendum: Since this case was observed I have heard of another death due to agranulocytosis following the therapeutic use of dinitrophenol by a middle-aged woman who had not been ill before the administration of the drug.

124 East Sixty-First Street.

2. Since this report was prepared there appeared in *THE JOURNAL*, on July 28, page 249, the case record of another, but nonfatal, case of agranulocytosis after dinitrophenol observed by Dr. S. Stephen Bohn.

Clinical Notes, Suggestions and New Instruments

A MECHANICAL DEVICE THAT PRODUCES UNIFORM DISPERSION OF BLOOD CELLS IN THE DILUTING PIPET

W. RAY BRYAN, PH.D. AND W. E. GARREY, M.D., NASHVILLE, TENN.

A study of the reports of leukocyte counts reveals contradictions and discrepancies that are clearly the result of faulty technic. A systematic study has revealed that a significant source of error is the failure to obtain a uniform dispersion of blood cells in the diluting pipet, which is reflected in variations of the numbers of cells as well as in their uneven distribution over the field of the counting chamber. Errors of surprising magnitude in the widely used manual method of shaking the diluting pipet in one plane were revealed in our study, and they were even more marked with certain mechanical shakers known to have been used in a number of research laboratories. The extent of the errors due to the use of a mechanical shaker is illustrated in table 1, which records typical results when as many successive counts as possible (nineteen) were made from the contents of a single pipet. It will be noted that the range between the minimum count of 6,480 cells and the maximum of 11,480 cells is 5,000 cells, while the coefficient of variation of the counts is ± 12.8 per cent in a series with an arithmetical mean of 8,716. It should be stated that similar unreliable results were obtained whether the pipet was continuously shaken or reshaken between successive counts, although two drops were always "wasted" before a drop was admitted to the counting chamber.

TABLE 1.—Dispersion of Leukocytes in the Diluting Pipet
Obtained by Means of a Mechanical Shaker,
Shakes the Pipets in Only One Plane*

* Showing the number of leukocytes on each square millimeter of area (of the fields of a counting chamber) obtained when as many counts as possible (nineteen) were made from the contents of a single pipet. Each total count is based on all the cells counted on one field, i. e., 9 sq. mm.

Potain, who devised the pipet with a bead in the bulb in 1862, specified the following method of mixing the cells: "Rotate the mélangeur around its axis and at the same time raise and lower its ends."¹ This technic, which was employed by Garrey and Butler in their recent studies, gives more consistent results than those obtained by either manual or mechanical shaking. The authors have devised a mechanical "rotor" which mixes the diluting fluid (Türks solution) and blood in the pipet by what is essentially the Potain method. The device

materially increases the accuracy of the counts. In its simplest form it may be assembled in any laboratory, as shown in figure 1. It is constructed from a large wooden spool on which wire or solder filament is wound. The spool (A), which has a diameter of $3\frac{1}{2}$ or 4 inches, is mounted on a shaft (B), which can turn on its axis by mounting through a bearing of brass tubing (C) at each end, the tubing being clamped (D) to the two uprights of a Jackson stand or any similar device. A pulley (E) on the shaft serves for a belt drive by an electric motor. The rotation of the spool must not be faster than 50 revolutions per minute; otherwise centrifugation of the cells will nullify the desired dispersion. Proper gearing is therefore essential. A satisfactory speed (42.8 revolutions per minute) has been obtained with an alternating current induction motor provided with the desired reducing gear (35 to 1) made by the Bodine Electrical Company (Type Car-2).

Fig. 1.—Simple rotor. A large spool rotated from 40 to 50 revolutions per minute by a motor with reducing gear and pulleys of proper ratio gives uniform dispersion of leukocytes in the pipet, which is attached at an angle to the axis of rotation. Lettering is described in the text.

The flanges of the spool are notched at several points to receive the pipets, which are mounted in the notches at an angle of 15 degrees and held in place by small rubber bands. Leakage from the pipets is prevented by stretching over their ends a wide rubber band or by the use of a collar device, such as is used with hematocrit tubes or such as is furnished with the Haak diluting pipet.

Figure 2 shows an improved mechanical rotor, which was built in the Vanderbilt Medical School Apparatus Shop by M. Herblin. This rotor is equipped with spring clamps, which will hold any commercial pipet in place. Leakage is prevented by means of thick rubber disks, placed in cups at each end of the clamp.

The principle involved in the use of this apparatus is that, owing to rotation, the cells settle by gravity in all possible directions and in ever changing planes, while at the same time they are stirred by the figure of eight movements of the glass bead.

Table 2 shows the results obtained in a typical experiment when as many counts (nineteen) as possible were made from the contents of a single pipet, mixing of the cells being

1. Tigerstedt, Robert: *Handbuch der physiologischen Methodik*, Leipzig, S. Hirzel, 1913, B: II 2, part 5, p. 11.

accomplished by means of the rotor device. The total white counts in this case with an arithmetical mean of 8,284, a minimum of 7,960 and a maximum of 9,120 vary over a range of only 1,160 cells, with a coefficient of variation of ± 3.4 per cent as compared to a range of 5,000 cells and a coefficient of variation of ± 12.8 per cent already noted when a mechanical shaking device was used (table 1). The compared counts of tables 1 and 2 were made from two pipets that were filled at the same time from the same sample of blood. A graphic representation of the distribution of cells on the fields of a hemocytometer is shown in figure 3.

* Showing the number of leukocytes on each square millimeter of area (of the fields of a counting chamber) obtained when as many counts as possible (nineteen) were made from the contents of a single pipet. Each total count is based on all the cells counted on one field, i. e., 9 sq. mm.

If the pipet is placed in the rotor immediately after the sample is taken and diluted, from five to ten minutes is sufficient to give an even dispersion of cells. However, if for

Fig. 2.—Improved form of rotor shown in figure 1. Extra pulleys to adjust the speed of rotation to about 50 revolutions per minute are shown. Described in text.

any reason the pipets must be kept for a while before the counts are made, thus allowing the cells to settle out, they may still be counted with the same degree of accuracy by being rotated for at least twenty minutes prior to the making of the counts. White blood cells begin to disintegrate after about twenty-four hours when diluted with Türk's fluid, but pipets may be allowed to stand for from twelve to eighteen hours and still may be counted with the same degree of accuracy as if counted immediately.

A statistical analysis of the results that we have obtained with this apparatus on more than 2,000 white cell counts is in progress and will be published subsequently, together with a study of other factors that influence the accuracy of the leukocyte count.

The distribution of red blood cells on the fields of a hemocytometer is likewise more uniform when the rotor device is used; however, certain precautions are necessary in the use

Fig. 3.—Frequency polygons, showing the variation in the number of cells in each square millimeter area of the fields of a counting chamber when as many counts as possible were made from the contents of a single pipet. The solid line shows the variation obtained when the cells in the pipet were mixed by means of the mechanical rotor (figs. 1 and 2). The broken line shows the more scattered results obtained when a pipet, which was filled from the same sample of blood, was shaken in a mechanical device which shakes in only one plane. Areas of 171 square millimeters (nineteen fields of a counting chamber) were counted in the case of each pipet.

of the diluting fluid. As formerly pointed out, Hayem's fluid develops a precipitate and after standing "should not be used in the case of blood samples which contain increased amounts of fibrin."² In our experience a large percentage of normal blood samples clump in the rotor device if Hayem's fluid is more than two or three weeks old, or if the fluid contains an excess of corrosive mercuric chloride. Freshly prepared Hayem's fluid gives excellent results. The tendency to clumping of the cells, due to the diluting fluid, is manifest in the case of the rotor device by balling up of the cells into clumps visible to the naked eye, so that they cannot be counted. In case the pipet is vigorously shaken the clumps are smaller, even microscopic, and, while the cells may be counted, accuracy of the results is nevertheless materially reduced. Other diluting solutions are being investigated.

SUMMARY

The mechanical device (rotor) and technic described add materially to the accuracy of the leukocyte count, give a greater constancy to the number and uniformity of distribution of these cells on the ruled field of the counting chamber, and permit repeated leukocyte counts of samples from a single pipet, even from twelve to eighteen hours after the dilution of the subject's blood has been prepared. Red cells may likewise be counted with greater accuracy, provided certain precautions are adhered to in preparation and use of the diluting fluid.

Judicious Blending of Science and Art.—One of the greatest problems of those engaged in the practice of medicine, is the judicious blending of the science and the art. After all is said and done, there is no antagonism between the science of medicine and the art of medicine and the most successful practitioner is he who most judiciously fuses them.—Blumer, George: Some Discursive Remarks on Bedside Diagnosis, *Yale J. Biol. & Med.* 6:571 (July) 1934.

THE EPIDEMIOLOGY OF AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

CHARLES F. CRAIG, M.D.

Professor of Tropical Medicine and Head of the Department of
Tropical Medicine, Tulane University of Louisiana
School of Medicine

NEW ORLEANS

The papers by Drs. Craig and Simon in this issue are part of a series of clinical lectures on amebiasis read at the Cleveland session. The other five papers, by Dr. Melency, Dr. Magath, Drs. Chesley and McCoy, Dr. Reed and Dr. Lynch, will be published next week and the week following.

In order to understand the epidemiology of amebiasis it is essential that one have a clear conception of the life history of the cause of the infection, *Endamoeba histolytica*. This organism belongs to the protozoa, or unicellular animals, and has three stages in its life cycle, a vegetative stage, during which it is known as a trophozoite; a precystic stage, and a cystic stage. It is essentially a tissue parasite, living in the tissues of the intestine of man, or elsewhere in the body, but also capable of life in the lumen of the bowel for a limited period of time at least. In the tissues of the intestine and in other tissues the amebas occur as motile trophozoites, and cysts are not formed in the tissues. In the feces during attacks of diarrhea or dysentery they occur also as motile trophozoites, although in very rich infections cysts may also be found in such stools, but usually the precystic and cystic forms are found only in semi-formed or formed stools. In the motile forms, reproduction occurs by simple division of the trophozoite into two amebas; no reproduction occurs in the precystic forms, while in the cysts the nucleus divides into four nuclei, cysts being found in the stools containing from one to four nuclei, the fully developed cyst having four. These cysts are the transmitting agents of the infection, as they are capable of resisting the gastric juice when swallowed in infected food or drink, while the motile forms are destroyed by the normal gastric secretion and hence are not infective. The cysts when swallowed pass unchanged through the stomach and greater portion of the small intestine, and in the lower portion of the ileum and the upper portion of the large intestine liberate a four nucleated ameba, which, after a complicated series of nuclear changes, divides into eight small amebas, which may invade the tissues or encyst and be passed in the stools of the host.

The methods of transmission of amebiasis depend on the fact that the cysts are the transmitting agents and that man becomes infected through the ingestion of food and drink contaminated by feces containing these cysts. As the cysts are seldom passed in any number in the stools of patients having acute diarrhea or dysentery, such patients are usually not infective, but it is the individual who is convalescent from dysentery, or who is apparently healthy or suffers from indefinite gastrointestinal symptomatology, who is a source of infection to those about him, as the cysts occur in semi-formed or formed stools in large numbers. As in practically

all untreated or improperly treated cases of amebic diarrhea or dysentery the cysts of this parasite are passed in the stool, it is evident that all such individuals become potential sources of infection, and the same is true of all individuals who harbor this parasite, regardless of the presence or absence of symptoms.

Amebiasis may be transmitted to man through a water supply polluted by feces containing the cysts of *Endamoeba histolytica*, through the use of human excreta in the fertilization of garden truck, through the handling of food by individuals who are excreting the cysts, and through the droppings of flies and perhaps other insects that have fed on infective material.

The transmission of amebiasis through a contaminated water supply is most apt to occur in rural regions where soil pollution is practiced and wells and springs are used as a source of water. It is probable that a large part of the incidence of this infection in country districts is due to contaminated water, as the cysts of this parasite will live in water for days, and even weeks, as proved by many authorities. That widespread infection with amebiasis may also occur in cities through a contaminated water supply has recently been demonstrated by the outbreak of amebic dysentery traced to contaminated water in certain hotels in Chicago, where, although food handlers undoubtedly played a part in the transmission of the infection, the water supply was apparently the chief factor in the transmission of the parasite. In this unique epidemic of amebic dysentery, defective plumbing and cross connections between the water supply of the hotels and the sewer were apparently responsible for extensive pollution of the water supplied the guests, with consequent transmission of the infection, although some transmission must have occurred through food handlers, as many of those employed by the hotels were found to be carriers of *endamoeba histolytica*.

Infection of man with *Endamoeba histolytica* is, under certain conditions, caused by polluted water; but infection from this source will not occur in localities where there is a properly impounded and filtered water supply unless this supply is polluted after leaving the filtration plant. It should be remembered, however, that the treatment of water with chlorine in order to kill disease-producing organisms is useless so far as amebiasis is concerned, for it has been repeatedly shown that the quantity of chlorine necessary to kill the cysts of *Endamoeba histolytica* is practically a hundred times greater than that used in water sterilization and that this agent cannot be used for this purpose. Boiling affords the only practical method of rendering water safe that has been contaminated with the cysts of this parasite.

Transmission of amebiasis through the use of human fecal material in the fertilization of truck gardens is a common method of transmission of the infection in the Orient, but even in this country this practice is not unknown and may be a method of transmission. The cysts of *Endamoeba histolytica* will remain alive in moist fecal material for as long as two weeks, and if this material is used in fertilization, and the vegetables so fertilized are eaten in an uncooked condition, it is obvious that there is great danger of the transmission of amebiasis in this manner.

The most common method of transmission of amebiasis, in otherwise well sanitized regions, is through the contamination of food and drink by food handlers

who are carriers of this parasite. Although recently there has been an effort made to minimize the danger of infection in this manner, it remains an incontrovertible fact that in cities and towns having an impounded and filtered water supply, and where sanitation is otherwise excellent, infected food handlers employed in hotels, restaurants, lunch counters and other public eating places are the chief source and transmitters of amebic infection. While the cysts of this parasite die rapidly after drying, and while the recent experiments of Spector and Buky¹ show that within ten minutes the cysts have perished after drying on hands experimentally soiled with feces containing them, this period is amply sufficient to infect food if the individual handles it directly after leaving the toilet. The transmission of this infection by food handlers who are uncleanly is practically a certainty unless the greatest care is taken regarding personal hygiene and the cleanliness of the hands, and it has been found that the incidence of this infection in food handlers employed in public eating places is often excessive, owing to their close association and the constant intake of cysts in the food that they themselves contaminate. There are many instances of record in which one infected food handler apparently infected many others in the same institution, and there is nothing more common than to find several members of a family infected if one member has been demonstrated to harbor the parasite. I have records of several families in which every member showed infection, and the infection could be traced to a cook who harbored the parasite. The infected food handler must still be regarded as the principal source of infection with amebiasis wherever the water supply is beyond suspicion, and even in regions in which water may be a potential source of infection a large part of the amebiasis present will have originated from infected individuals engaged in the preparation and handling of food.

The contamination of food and drink by the droppings of flies is sometimes a method of transmission where flies are very plentiful and have access to fecal material. The cysts of *Endamoeba histolytica* remain viable in the intestine of these insects for as long as forty-eight hours, during which time the droppings of the insect contain them, and food may be thus contaminated. It is impossible to say just how important this method of transmission may be but, under certain conditions, as in military operations or large construction problems where many men are collected together, fly transmission may become a very important method of transmission.

The question of the possible existence of strains of *Endamoeba histolytica* differing in virulence is one that deserves consideration, and recently Meleney and Frye² have brought forward some evidence favoring variations in virulence of certain strains of the parasite with which they have infected kittens. While the theory of variations in virulence in strains of *Endamoeba histolytica* is an attractive one and one that would explain some of the puzzling differences observed in the symptoms attending human infection, it must be admitted that up

to the present time such evidence as is available is not sufficient to offset the results of the many investigations which have apparently demonstrated that there is no difference in virulence between strains of this parasite isolated from symptomless individuals and those suffering from severe attacks of amebic dysentery. The only successful experiments in the production of amebic dysentery in human volunteers, those by Walker and Sellards,³ were obtained by feeding cysts of *Endamoeba histolytica* obtained from symptomless carriers of the parasite. It is probable that the explanation of the variations in the severity of the symptoms produced by *Endamoeba histolytica* in man depends on the number of cysts ingested and the resistance of the individual rather than on differences in virulence of the parasite, although further work needs to be done along this line before such differences in virulence can be denied.

While under ordinary conditions the symptom complex of amebiasis known as amebic dysentery usually occurs in the form of sporadic cases, it may occur in epidemic form if conditions as regards lowered resistance or massive dosage of cysts are present. The epidemic occurrence of amebic dysentery was observed repeatedly among troops operating in the field in the Philippines, when resistance was lowered by the conditions present in active field operations and constant reinfection by swallowing numerous cysts in highly polluted water occurred. The recent outbreak of amebic dysentery contracted in certain hotels in Chicago is another instance of the epidemic occurrence of this condition when massive infection is possible. However, it is most unusual to encounter epidemics of this type of dysentery, and it is well to remember that the vast majority of cases of amebic dysentery occur sporadically and in this feature differ from bacillary dysentery, which very frequently occurs in epidemic form.

As regards climate, amebiasis is not a tropical disease, and its most serious manifestation, amebic dysentery, occurs throughout the world, although more frequently observed in the tropics because of greater chances of heavy infections and the lowered resistance of the inhabitants. It is true that heat and humidity appear to favor the development of symptoms in individuals harboring *Endamoeba histolytica* and that removal of patients suffering from amebic dysentery to a cool climate is generally followed by a marked improvement in their condition; but this is believed to be entirely due to the increase in the resistance of the individual following the stimulating effect of the change to a cooler climate.

There is no good reason for believing that this infection even originated in the tropics or subtropics, for *Endamoeba histolytica* has been found wherever it has been looked for, and the first case of amebic dysentery ever described was in a resident of St. Petersburg, Russia, who had never been in the tropics. It is also true that amebiasis and amebic dysentery have been occurring in the United States for many years and that the impression which some physicians have that this is a recently introduced infection is far from the truth. It is probable that amebiasis has always been present in this country but has been unrecognized, and careful observation will certainly demonstrate that it is much more prevalent than has been believed.

1. Spector, Bertha K., and Buky, Florence: *Viability of Endamoeba histolytica and Endamoeba coli: Effect of Drying*, Pub. Health. Rep. 49: 379 (March 23) 1934.

2. Meleney, H. E., and Frye, W. W.: *Studies of Endamoeba histolytica and Other Intestinal Protozoa in Tennessee*, Am. J. Hyg. 17: 637 (May) 1933.

3. Walker, E. L., and Sellards, A. W.: *Philippine J. Sc.* 8: 253, 1913.

So far as its epidemiology is concerned, it differs but little from that of the epidemiology of most infections contracted through infected food or drink, and the measures that have been found successful in preventing infection with these diseases will prove equally effective in combating amebiasis. The first essential is the recognition by the physician and public health officer that this infection is a prevalent one in this country, with a thorough understanding of its nature and the methods of transmission.

THE CLINICAL DIAGNOSIS OF AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

SIDNEY K. SIMON, M.D.
NEW ORLEANS

From a clinical point of view, the most characteristic feature of amebiasis is embodied in the wide variability of its manifestations. The course pursued by the disease exhibits a symptom complex of highly diverse and changeable character, ranging in varying degrees of severity from attacks of a virulently acute fulminating colitis, such as occurred in the Chicago episode of 1933, to mild and all but negligible forms of bowel derangement. Moreover, fairly extensive lesions are found to occur along the intestinal tract without producing any striking symptoms or positive evidence of their presence. The first detailed description of the condition was undertaken by Councilman and LaFleur¹ in 1891 under the title of amebic dysentery. This designation is now regarded as not sufficiently accurate and in many respects as misleading, in view of the present knowledge that the occurrence of typically dysenteric as well as other intestinal phenomena comprises only a relatively small part of the composite picture of an amebic infestation. At least 50 per cent of individuals who harbor pathogenic amebas, in fact, never become cognizant of the presence of the organisms within the body. This group of so-called symptomless or healthy carriers nevertheless usually display some ill effects of their infection, even though slight. Indeed, invasion of the structures of the body by *Endamoeba histolytica* constitutes a definite clinical as well as pathologic entity, irrespective of whether manifestations are present or not.

ETIOLOGIC FACTORS

The cause of the variable degrees of severity exhibited by the disease and the inconstant and irregular character of the clinical picture as a whole may be ascribed to one or more of several contributory factors: 1. The site of location of the active pathologic lesions in the colon as well as the total area of bowel involvement are both factors of considerable clinical importance. In general, the nearer the lesions invade the region of the rectum and sigmoid, the more manifest are the intestinal symptoms. 2. The numerical concentration of cysts of *Endamoeba histolytica* present in contaminated water or food supplies furnishes a

source for the rapid development at times of a virulent type of infection. Such conditions are encountered most often in military units but may also occur in civilian groups when insanitary living facilities prevail, as was the case in the recent Chicago outbreak. 3. An incidental bacterial infection superimposed on an amebic invasion of the bowel often gives rise to complexities in diagnosis. This double or crossed type of infection involving most frequently organisms of the *Bacillus dysenteriae* group serves to intensify and at times to mask the true picture of amebiasis. 4. The reaction of the human host to the invasion of the pathogenic amebas, in this as in other infectious processes, determines in great part the degree of severity and the clinical tendencies displayed by the disease. A relative as well as an absolute immunity is manifested in amebiasis, notably in certain racial strains as well as under varying circumstances of prolonged exposure to the infection, climate, age, sex and physical fatigue. 5. The varying changes of morphology that the organisms undergo during the evolution of their life cycle within the tissues exercise a measurable influence on the clinical phases of the disease. These changes range from the stage of motile activity of the vegetative cycle, accompanied by further tissue invasion and necrosis, to the stage of encystment wherein the organism is rendered completely innocuous to its original host.

CLINICAL GROUPS

These fundamental predisposing factors, briefly surveyed, afford an insight into the changeable conditions that surround the clinical course of amebiasis. The kaleidoscopic picture can be outlined best, it would seem, by a division into several more or less well defined clinical groups, as follows: 1. Acute fulmination amebic colitis, which originates, as a rule, spontaneously from a definitely traceable source of infection. These cases appear commonly in virulent epidemic form and yield a high rate of mortality. 2. The relapsing stage of chronic intestinal amebiasis. Acute and subacute sporadic attacks occurring in this group seldom attain the high degree of intensity observed in the primary or epidemic type. 3. Chronic amebic colitis exhibiting active clinical phenomena over a period of several months or years. During the prolonged clinical course, intercurrent attacks of dysentery or diarrhea as well as other manifestations appear, which alternate with irregular periods of quiescence. 4. The nonactive or latent type of infestation with *Endamoeba histolytica*, which includes the relatively large numerical group of innocent carriers of the infection. These individuals, while they do not display outspoken evidence of their infection, nevertheless in most instances exhibit certain departures from normal health standards. 5. A group of atypical clinical conditions not associated with disturbances of bowel function but none the less traceable in origin to the presence of pathogenic amebas within the structures of the body.

ACUTE AMEBIC COLITIS

Experimental investigations in lower animals have demonstrated that infection of the colon with *Endamoeba histolytica* does not bear any constant relationship to the time of onset of clinical symptoms. The period of incubation in man likewise remains uncertain

Read before the General Scientific Meeting at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 12, 1934.
1. Councilman, W. T., and LaFleur, H. A.: *Johns Hopkins Hosp. Rep.* 2: 393, 1891.

and from the clinical side can rarely be determined with any degree of accuracy. As far back as 1913, Walker and Sellards² were able to carry out experimental tests with twenty volunteer prisoners in the Philippine Islands, who were made to swallow fecal material containing cysts of pathogenic amebas. Of these, eighteen were successfully parasitized with the organisms. Subsequently, in four of these eighteen individuals, or approximately 22.2 per cent, typical symptoms of intestinal amebiasis developed. The incubation period of these four cases turned out to be twenty, fifty-seven, ninety-five, and eighty-seven days respectively, yielding an average of 64.8 days for the series. As far as I have been able to learn, no subsequent series of human tests of this character have been carried out. In the recent Chicago outbreak, virulent symptoms developed in several patients within two weeks following their exposure to the infection. The source of the infection proved to be a contaminated water supply, which, while comparatively free of bacterial organisms, contained vast numbers of the cysts of *Endamoeba histolytica*.

The onset of an attack of acute amebic colitis is usually quite sudden but may be preceded by a diarrhea of a few days' standing. In the fulminating types, the bowel evacuations rapidly assume a mucoid and bloody appearance and are accompanied by a marked degree of tenesmus. The rectal straining along with frequency of the stool passages advance to a state that compels the patient to remain more or less constantly on the bed pan or become "glued to the pot," as the English express it. Abdominal cramps precede and accompany the appearance of the dysenteric stools. Evidence of constitutional toxemia sets in at an early stage, so that the patient is frequently transformed from good health into a virulently ill individual within a few hours. The range of temperature varies but from the onset may assume an elevation from 103 to 105 F. Marked physical prostration with mental hebetude completes the picture of the rapid absorption of toxic bodies from the highly inflamed and, in some instances, gangrenous bowel surfaces. Death may ensue within the first few days of the onset, but in cases showing a favorable outcome improvement becomes evident about the fourth or fifth day of the illness. Microscopic examination of the evacuations reveals the presence of desquamated epithelium, large phagocytic cells, red blood corpuscles and leukocytes, in addition to the motile vegetative amebas. During the initial period of the acute attack, amebas, however, may be found missing from the stool even after careful search has been made. This constitutes a point of great importance, especially in fulminating cases, since a positive diagnosis of amebic infection must be withheld until the specific organism can be demonstrated in the dejecta. Further confusion is entailed in this respect because of the close similarity that obtains between the clinical characteristics of acute bacillary dysentery of various strains and acute colitis of amebic origin. Cross infections occur quite frequently and are probably always the rule in fulminating amebiasis. In four cases reported by Lund and Ingham³ with fatal termination, pathogenic amebas were dis-

covered in the bowel only at autopsy, though repeated stool examinations had previously been conducted. Weinberger⁴ recently recorded two cases of acute bacillary colitis in which vegetative endamebas were subsequently found two and one-half months after the onset of the illness. When doubt exists regarding the presence of a double infection, most authorities agree that hypodermic medication with emetine hydrochloride is indicated tentatively to control the possible amebic involvement.

Fortunately, in the acute relapsing stages of a chronic amebic colitis, the protozoal organisms can be found in the feces more uniformly and with greater facility. The symptoms likewise fail to attain the degree of severity witnessed in the fulminating or primary type, except on rare occasions. Indeed, the dysenteric features may be absent entirely or may be replaced by a simple diarrhea. The frequency with which relapses occur in chronic amebic infection of the colon varies considerably. Indiscretions in diet, changes in atmospheric conditions and prolonged physical fatigue stand out as among the principal contributory factors in the production of acute or subacute outbreaks.

CHRONIC AMEBIC COLITIS

In the vast majority of instances, amebiasis of the colon is revealed as an essentially protracted infectious process, largely of undetermined origin and inception. A careful analysis of many case records will, however, disclose a history of mild degrees of clinical derangement long before the onset of the more typical intestinal disturbances. In one of my own cases presenting healed hepatic abscess, I was able to trace the amebic invasion back forty-three years. Large numbers of individuals infested with *Endamoeba histolytica*, as previously stated, fail to show any appreciable clinical evidence pointing to the presence of the organisms. On the other hand, the infection may light up quite suddenly into a highly acute form after having remained dormant for a long time. Even during the less active periods, however, the disease still carries harmful potentialities, since remote complication of serious character, such as hepatic abscess or perforation, may occur without the intervention of previous intestinal symptoms. The clinician should never be led into error by the uncertain or changeable course of the disease. Neither should a prompt subsidence of symptoms be regarded as evidence of recovery from the infection. In the past, many widely heralded cures have been recorded as a result of the employment of certain amebicidal agents. On further study, a large percentage of these prove to be mere examples of the conversion of the active symptom picture of the disease into one of relative quiescence. Indeed, the simple expedient of placing the patient in bed on a restricted diet will in many instances prove sufficient to allay the immediate irritable bowel disturbances.

Apart from the occurrence of intestinal manifestations, other clinical features are commonly found to be associated with a protracted state of infection induced by *Endamoeba histolytica*. The character of these disturbances consists, in the main, of functional neuroses of various kinds, digestive disabilities, secondary ane-

nia, loss in weight, physical fatigue, and a general impairment of bodily strength. As far as the digestive sphere is concerned, patients complain vicariously of anorexia or a capricious appetite, bad taste, acid eructations and heartburn, and occasionally nausea and vomiting. These symptoms may be traced for the most part to the presence of a particularly obstinate form of constipation, a condition that is quite common during the less active phases of amebiasis. Evidence of functional neuroses is frequently present in other organs of the body apart from the digestive tract. These are to be ascribed in great part to the absorption of toxins from the submerged areas of ulcerative lesions in the intestinal wall. Severe grades of anemia are rarely encountered in amebic infections, though the oozing of blood from the surface ulcerations, combined with the attending constitutional toxemia, is capable of producing a definite chloranemia. Changes in the number or character of leukocytes is rarely observed during the normal course of an intestinal amebiasis. When leukocytosis does occur, it indicates either the occurrence of a mixed infection with bacilli or a remote complication such as hepatic abscess, appendicitis or perhaps localized or general peritonitis. Loss in weight and the lowering of the health standard in general are phenomena not infrequently found in connection with the disease. In a series of 217 cases that I⁵ studied a few years back there was an average loss in weight of 12 pounds (5.4 Kg.) covering the recognized period of duration of the disease.

CLINICALLY ATYPICAL AMEBIASIS

Unusual clinical types occur in amebiasis with sufficient frequency to justify a separate grouping. The chief characteristics of these cases lie in the fact that knowledge of the existence of an amebic infection of the bowel could scarcely have been obtained from the clinical history or the physical state of the patient. On the contrary, these are in many instances rather of a contradictory nature. Because of this, reliance for the diagnosis of all clinically atypical amebic infections must be placed on the detection of pathogenic amebas in the stool passages. This does not exercise any undue clinical hardship, however, since at the present time routine fecal examinations have become a necessary adjunct to every diagnostic study. In an article published in 1926 I⁶ described in detail a group of unusual clinical types of amebiasis. Each of these cases presented, in turn, a perplexing clinical problem, previously unsolved and entirely apart from any disturbance within the intestinal tract.

The following comprise examples of the type of symptom complex one may encounter in cases of atypical amebiasis of the colon: pain of indefinite character localized in various sections of the abdomen; spurious appendical phenomena, which not infrequently have led to unnecessary operative intervention; pains of the boring or aching type in the lumbar and sacral regions not associated with orthopedic disability; low grade daily temperatures accompanied by marked physical fatigue which suggest low grade infectious states, as tuberculosis; persistent and unexplained loss of weight; secondary anemias of marked degree showing lack of

therapeutic response; massive hemorrhage from the bowel without an explainable cause; attacks of nausea and vomiting, sometimes of long duration, without demonstrable etiology except the accidental discovery of amebic infestation of the colon. The clinical manifestations in such cases as have come under my observation have subsided promptly following the employment of amebicidal agents. In fact, the results in some instances have proved quite fantastic. Brown⁷ has recently reported five cases of atypical amebiasis, yielding satisfactory therapeutic results, in which he lays particular stress on the responsibility of the clinician for maintaining a low "threshold of suspicion" in the search for amebic infestation.

DIFFERENTIAL DIAGNOSIS

In its purely clinical aspects, amebic colitis possesses a close similarity to a number of other disease conditions of the lower portion of the bowel. In the acute stage, confusion is frequently encountered in connection with the acute bacillary dysenteries, and acute ulcerative colitis of varied etiology, as well as certain types of acute enterocolitis arising from infectious or toxic sources. The differential diagnosis of chronic amebiasis is also beset with difficulty in some instances, principally in respect to certain ulcerative and infiltrative lesions of the upper and lower portions of the bowel, as follows: chronic bacillary dysentery, chronic ulcerative colitis due to a number of causative agents, carcinoma of the rectum and lower portion of the bowel, intestinal tuberculosis, recurrent acute and subacute appendicitis, chronic ileitis, sprue, pellagra and balantidiosis, in addition to flagellate infections of the bowel.

No attempt will be made to discuss the points of difference that distinguish these various clinical states. It suffices to comment, at present, however, on the all too frequent errors in diagnosis disclosed in the case histories of amebic patients. In earlier periods the recognition of amebic infestation was overlooked by a large percentage of the profession in spite of repeated warnings as to its universal distribution. Since wider knowledge of the disease and its possibilities has been attained in recent times, however, many intestinal lesions have been diagnosed as amebic in origin which have in fact no connection with the organism. During the past year I have myself encountered ten cases of carcinoma of the lower portion of the bowel that had been treated persistently for months for amebiasis. Again, it is not an uncommon experience to observe patients showing definite evidence of amebic ulceration of the bowel, who had undergone operations previously for hemorrhoids or other rectal lesions. The clinician has to be on guard, therefore, both in his failure to find the infection and in mistaking amebiasis for other conditions.

DIAGNOSTIC CRITERIA

In the ultimate analysis the diagnosis of amebiasis in the living subject must devolve on the detection of the specific organism in the bowel passages. Under no circumstances should reliance be placed on the clinical phenomena alone, no matter how suggestive they might prove to be. The discovery of vegetative or encysted endamebas may be accomplished either by direct micro-

scopic examination of specimens of the bowel evacuations or from cultures of the suspected feces. The latter plan of cultivating the organisms in specially prepared mediums has been perfected in more recent times, largely through the work of St. John.⁸ This method, though it yields a high degree of diagnostic accuracy, unfortunately lies beyond the reach of the average practitioner of medicine. A similar disadvantage may be said to surround the complement test of blood serum, which was devised by Craig⁹ and has been employed by him and others with great success in the diagnosis of ameba infested subjects.

The great problem in amebiasis, it would seem at the present moment, is to find ways and means to enable the great army of clinicians to recognize the disease more accurately and with greater facility than has obtained in the past. The scope of such a plan must necessarily center on the microscopic examination of the stools. Contrary to the opinion expressed by many laboratory workers, I do not believe that extensive technical training is needed for the recognition of pathogenic amebas either in the vegetative or in the encysted form. The ideal method is to have the clinician conduct his own examination of the feces with the patient directly at hand. If ambulant, he should be asked to bring the fecal specimen, whether formed or not, to the office. This is examined carefully for the presence of vegetative amebas or cysts. The following day the patient is required to take a saline cathartic and to appear for proctoscopic examination shortly after the appearance of the first watery bowel passages. Rectal examination through the proctoscope will reveal the presence or absence of ulcerative lesions of the lower portion of the bowel and at the same time afford an opportunity to procure scrapings of the bowel surface as well as specimens of the soft or watery stool for detection of the motile vegetative organisms. Repeated examinations are necessary in some cases before a positive diagnosis can be ruled out.

The character of the ulcerative lesions in amebiasis, as viewed through the proctoscope, can in no manner be considered pathognomonic. The more typical type presents a deeply punched out appearance, with ragged overhanging edges. The base of the ulcers is covered, as a rule, with a thick, yellow, purulent secretion. The ulcers and mucous surfaces of the bowel wall can be made to bleed readily by the slightest trauma. The proctoscope picture, it is well to remember, represents merely surface ulcerations and is not to be confused with the true pathologic lesions of the disease, which are infiltrative in character and are located chiefly in the submucosa. Moreover, in the vast majority of individuals who harbor *E. histolytica*, no visible evidence of the infection can be found by rectal examination.

The x-rays have been called into service to assist in the differential diagnosis of amebic infiltration and ulceration of the bowel wall as distinguished from other lesions in the colon. Marked thickening of segments of the colonic wall as well as deeper areas of ulceration can usually be detected readily by a radiologic examination. However, this cannot be made the basis for the diagnosis of specific amebic involvement when other clinical and laboratory signs fail.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed.

THERAPY OF CARBUNCLE

Carbuncle is a deep seated intradermal staphylococcal infection, which differs from furuncle (q. v.) in being characterized by multiple foci of necrosis and terminating in gangrene. Because of radical difference of treatment, malignant pustule, or anthrax (q. v.), must be differentiated from carbuncle. Anthrax is characterized by the early formation of a blister and of a hard, black, painless and insensitive slough that becomes surrounded by a halo of vesicles, in the fluid of which smears show anthrax bacilli. History of exposure to infected animals or animal products may lead to suspicion of anthrax.

LOCAL TREATMENT OF CARBUNCLE

There is no use in wasting time with hot moist dressings. Possibly roentgen irradiation (300 roentgens, 140 kilovolts, with a filter of 0.25 mm. of copper and 1 mm. of aluminum) may be of value if the case does not seem ripe for radical treatment.

Surgical Treatment.—Crucial incisions are made, excepting in carbuncle of the lip, which is treated like furuncle of the lip (q. v.). Under general (not local) anesthesia and as soon as there is a point of softening, the indurated area is incised from sound skin to sound skin by crucial incisions clear through the derma and down to the deep fascia. The points of skin are raised with toothed forceps and the subcutaneous trabeculae are severed, thus undermining the skin to tap the collections of pus. The points of the skin flaps as well as all necrotic tissues are then excised to leave a wide opening for drainage and the extrusion of the slough. Pockets containing necrotic material that cannot well be excised are curetted. The cavity is then cauterized with Liquefied Phenol, which is removed after a minute by means of an alcohol-saturated tampon. The cavity is finally packed with iodoform gauze and hot boric acid dressings are applied. At change of dressing, instillation of Solution of Hydrogen Dioxide and irrigation with hot Physiologic Solution of Sodium Chloride may help in the separation of the sloughs. The ulcer remaining after the sloughs have been discharged is treated in accordance with general principles (see Therapy of Ulcers).

Magnesium Sulphate-Phenol Paste

℞ Dried magnesium sulphate.....	75.00 Gm.
Liquefied phenol	10.00 cc.
Glycerin	90.00 cc.

Mix in a hot mortar, with a hot pestle, and keep in a tightly covered jar to prevent absorption of moisture.

Label: Apply on lint to cover the whole of the affected area, and cover with a thick pad of absorbent cotton.

Analgesic Paste Dressing.—Until surgical treatment can be applied and when it is contraindicated, the magnesium sulphate-phenol paste dressing gives some relief

8. St. John, J. H.: *Am. J. Trop. Med.* 6: 319 (Sept.) 1926.

and, being hygroscopic, tends to convert the moist into dry gangrene. After the skin is defatted with ether, the paste, spread on lint, is applied to the whole area and covered with a thick layer of cotton. This dressing is removed at least every twenty-four hours, until the sloughs have separated.

SYSTEMIC TREATMENT

Absolute rest in bed and of the affected part is essential. Nutritious food should be given and morphine administered as required for pain (q. v.). Bowel and kidney function should be maintained. For diabetic patients, insulin therapy (q. v.) should be given energetically.

PROPHYLAXIS

For prevention of recurrence, the same methods are employed as in the prophylaxis of furuncle (q. v.).

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

BISMUTH SUBSALICYLATE (See New and Non-official Remedies, 1934, p. 116).

The following dosage form has been accepted:

Bismuth Subsalsicylate with Butyn-D. R. L.: A 10 per cent suspension of bismuth subsalsicylate-U. S. P. in peanut oil to which has been added 0.6 per cent butyn and metaphen 1:20,000. Each cubic centimeter represents from 0.057 to 0.059 Gm. of elemental bismuth. The product is marketed in bottles containing 60 cc.

Prepared by the Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1934, p. 61).

The following additional dosage forms have been accepted:

Ampoules Procaine Hydrochloride Solution 10%, 2 cc., For Spinal Anesthesia: Each cubic centimeter contains procaine hydrochloride, 0.1 Gm., dissolved in distilled water.

Ampoules Procaine Hydrochloride Solution 2%, 5 cc.: Each cubic centimeter contains procaine hydrochloride 0.02 Gm., dissolved in physiologic solution of sodium chloride.

Procaine-Epinephrine Solution, 100 cc. Bottle: Each cubic centimeter contains procaine hydrochloride 2%, epinephrine 0.04 mg. (1/4,000 grain), sodium bisulfite 0.001 Gm., in isotonic solution.

Procaine Hydrochloride Hypodermic Tablets 1/2 grain.

Procaine Hydrochloride Hypodermic Tablets 3 grains.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

ERYSIPELAS AND PRODIGIOSUS TOXINS (COLEY)

Sir James Paget is said to have first called attention to the occasional spontaneous remission of malignant tumors following attacks of acute febrile conditions, particularly erysipelas. As early as 1882 Fehleisen,¹ who discovered a streptococcus as the cause of erysipelas, employed living cultures in the treatment of cancer with beneficial results in some instances. In 1891 Lassar and Spronck¹ advocated the use of killed cultures, while in this country W. B. Coley published some observations on the action of viable streptococci in the treatment of sarcoma. The use of such preparations did not achieve widespread popularity, nor has it up to the present, in spite of the fact that many noteworthy cures have been reported in seemingly hopelessly inoperable cases. From its inception,

however, Coley has pursued the method avidly and has published reports of extensive series of cases, as well as developing the combined toxins of *B. prodigiosus* and *Streptococcus erysipelas*. The latter preparation was suggested by the observations of Roger,¹ who found that the toxins of the former materially enhanced the virulence of experimental erysipelas in rabbits. By 1910 the preparation "Erysipelas and Prodigiosus Toxins-Coley" had been sufficiently investigated to warrant its inclusion in N. N. R.² At that time it was estimated to effect a cure in from 4 to 9 per cent of cases of inoperable sarcoma. Under "Actions and Uses" in New and Nonofficial Remedies the following statement was made originally:

It is therefore likely that the treatment of inoperable sarcoma with the toxins of erysipelas and *B. prodigiosus* leads to a cure in approximately 4 to 9 per cent of cases. And some results obtained so far suggest that this method of treatment may prove of value as a post-operative procedure in diminishing the number of recurrences, and that in a certain number of cases it might limit the necessity for amputation of the limb in cases of sarcoma of the long bones. As to its mode of action nothing definite can be stated, but it is likely that the toxins themselves, as well as the local and general reactions they produce, frequently affect the life of the sarcoma cells unfavorably.

This statement was revised to a more concise form, of the same import, in 1914 and has remained in N. N. R. for twenty years with no further change:

Its use has been advised in cases of inoperable sarcoma. This remedy is said to have benefited and produced cures in a small percentage of cases treated, though there is some difference of opinion as to this.

Because of this relatively indefinite status of the product, it was deemed expedient at the time of its reconsideration this year to review the situation with a view to the elaboration of a more specific and explicit estimate of the therapeutic utility of the preparation and of its limitations. As is the case with many drugs, the determination of efficiency in terms of the proportion of successes to failures is most difficult, owing to the tendency on the part of students and investigators to report, predominantly, only the former.³

One of the earliest reliably recorded failures is a case of sarcoma of the scapula observed by Babcock and Pfahler,⁴ wherein excision had been attempted four times with recurrence after each attempt. When, finally, the condition attained a frankly inoperable state the authors resorted to irradiation and certain of the therapeutic fancies then in vogue, such as trypsin, methylene blue and Doyen's serum.⁵ Through all this the patient failed rapidly and the scapular mass attained the size of a "man's head." Seven days prior to death, huge doses of Coley's toxins were employed and probably served only to hasten the inevitable outcome. This case is typical of many of the reported failures in which the toxins of erysipelas and prodigiosus were instituted when the patient was moribund. In view of the prolonged treatment that has been employed in the successful cases, it is only reasonable to predict certain failure if the immediate temporal outlook for survival is not sufficiently long to allow of an adequate course of therapy.

Spencer⁶ observed a case that well illustrates the point under discussion. The patient had a large inoperable mass of undetermined origin occupying the entire lower abdomen and infiltrating various viscera and the parietes, including the rectus muscle.⁷ Biopsy, taken at operation, showed the tumor to be a spindle-cell sarcoma. Coley's toxins were employed in dosage of from one-half to three minims on alternate days for twelve doses with no apparent effect. The patient left the hospital very emaciated with a fatal prognosis, only to return two months

2. Report of the Council on Pharmacy and Chemistry, J. A. M. A. 54: 290 (Jan. 22) 1910.

3. Effort has been made throughout to include only those cases which have been found to be adequately recorded according to present-day custom. About eight of every ten reported prior to 1920 were found to present shortcomings sufficient to preclude their consideration as valid, incontrovertible evidence.

4. Babcock, W. W., and Pfahler, G. E.: A Conservative Treatment of Sarcoma, Pennsylvania M. J. 11: 849, 1907-1908.

5. Trypsin was employed by direct application in an attempt to "digest" the tumor mass. Doyen's serum was a serum prepared by the immunization of animals to organisms isolated from tumor tissue; the so-called Doyen's bacillus which was supposed, by Doyen, to bear some etiologic relationship to malignant processes.

6. Spencer, C. G.: A Case of Sarcoma Treated with Coley's Fluid, Proc. Roy. Soc. Med., London 2: 152 (Clinical Section) 1909.

7. It seems likely that this may have been a tumor of a persistent urachus.

1. Cited by Loeh, Leo: The Treatment of Inoperable Sarcoma by Erysipelas and Prodigiosus Toxins, J. A. M. A. 54: 262 (Jan. 22) 1910.

later showing a gain of 15 pounds (6.8 Kg.) and the ability to take active exercise. The mass was still present, though greatly diminished in size. Thirty-four more injections were given into the mass or intramuscularly throughout the ensuing three months, during which time the mass entirely disappeared. The patient returned to active army life and was reported free of recurrence and well at the time of writing, two years later. Spencer's paper includes two other cases similarly and successfully treated, each shown in biopsy to be fibrosarcoma, one of the tonsil (which had recurred following each of three attempts at surgical eradication) and the other of the sheath of the femoral artery (with tumor thrombus) in which operation was refused.

Green⁸ reported a series of three cases in which the patients were living and well from three to ten years following treatment with the Coley toxins. Two of these, giant cell sarcomas of the shoulder, were deemed inoperable when first seen. The third, a small round-cell sarcoma of the femur, recurred after operation. Injections were made directly into the tumors as well as intramuscularly at a distance. Disappearance of the masses and complete healing took place within three months in all cases, although the toxins were continued another three months thereafter. Soper⁹ records two cases in which amputation was followed by recurrence. The patients were alive and well six years after intensive and prolonged administration of the toxins. In one of these cases a spindle-cell sarcoma of the scapula exhibited recurrence in the posterior chest wall after total excision of the pectoral girdle on the affected side. In the other, a periosteal sarcoma of the hip joint was probably inoperable at the time amputation was performed and pelvic recurrence ensued promptly. Newcomet,¹⁰ however, reports a uniformly fatal issue in each of three inoperable cases with the combined use of the toxins and irradiation; he concludes that the toxins served merely to hasten the fatal issue. Odier¹¹ arrives at the same conclusion following his report of one case so treated.

During approximately the same time that the foregoing papers were appearing, Coley was enjoying a wide experience with the product and numerous of his reports were published.¹² In 1925 he reported¹³ sixteen cases with more or less thorough roentgenographic and pathologic studies. However, in 1926 and 1927 a most comprehensive review¹⁴ of 171 cases was presented by the same author, including a later follow up of many of the cases previously reported. In all instances the tumors were of the giant-cell, spindle-cell or periosteal-osteogenic type of sarcoma. This series included only sarcomas of long bones, in 111 cases of which toxins were administered alone or combined with amputation or with irradiation or with both, while in the remaining sixty, aside from biopsy, no initial treatment was given other than with radium or the roentgen ray. The distribution in either group as to the type, duration and location of the tumors is fairly equable, sufficiently so to warrant certain conclusions from the results as tabulated in a variety of ways. Of sixteen patients subjected to amputation with no other preliminary or postoperative treatment, fourteen were dead within a year, one died of pulmonary metastasis seven years later, and the other died of recurrence in the calvarium five years later. Thus, but two (or 12.5 per cent) of sixteen patients lived three years or longer, with seven years being the maximum period of survival. Of thirty-nine patients given the toxins following amputation as "prophylaxis" against recurrence, twenty (or 51 per cent) are reported alive and well from four to twenty-eight years later, with an average duration of survival when last reported of over eleven years. Of thirty-

two patients living and well five years or more (average 11.7 years), all had received the toxins at one time or another (although irradiation and amputation may have been employed conjointly). In this group the limb was saved in fifteen cases (47 per cent) and sacrificed in five. Of twenty-nine patients receiving irradiation originally and amputation subsequently, if necessary, twenty-one died within a year, seven were alive from one to three years later, and one case was too recent to merit consideration.

Lilienthal¹⁵ reports a well studied case of a female infant of 22 months suffering from a large mediastinal mass with extensive invasion of either lung. To reduce cardiac compression, a portion of the tumor was excised with, of course, no attempt at eradication. A diagnosis of angiosarcoma was made by F. S. Mandelbaum, of hemangioendothelioma by Louis Gross, and of malignant cellular tumor of embryonal type by James Ewing. The toxins were begun and continued for eleven days (increasing from one-fifth minim to 4½ minims), when the mother refused further treatment because of the severe reactions. Roentgenographic examination over two years later demonstrated the chest to be essentially normal in every respect, with no indication of the original process. Quite as thoroughly studied is the case of Christian and Palmer,¹⁶ who record the occurrence of myelosarcoma of the tibia, on a chronic osteomyelitic basis, in a master mariner of 31 years. This diagnosis was concurred in by Ewing and Codman. Mid thigh amputation was performed, but three months later a mass appeared just above the umbilicus and a month thereafter nodules had developed in the groin and the stump. The toxin treatment was instituted with an initial dose of one-fourth minim, increasing to 6½ minims daily. In seventeen days the circumference of the stump had decreased 2 inches (from 19 to 17 inches), the mass in the groin had disappeared and the supra-umbilical metastasis was distinctly smaller.

The dose was kept at 6½ minims a day for the ensuing week, when a daily increase of 1 minim was instituted and maintained until, finally, a dose of 18 minims was being administered. Because of severe emaciation, medication was discontinued after three weeks of the increased dosage, at which time the stump had resumed growth and considerable edema had appeared both in the stump and in the sound leg. Throughout the ensuing four months the patient's course was extremely retrograde; multiple metastases appeared in the abdominal wall, clavicles, sternum, scalp, cranium and the cervical vertebrae. The stump attained a circumference of 31 inches (almost twice the original size) and its end presented a large, necrotic area. Roentgen examination barely revealed the outline of the femoral cortex, the remainder of the bone having been completely destroyed. As a last resort the Coley toxins were begun once more, starting with 2 minims and increasing rapidly to 17, where they were maintained for one month and, following a two weeks rest, again instituted for another three weeks. At this time the stump had healed completely and had returned to its normal size (17 inches); all evidence of metastasis had disappeared except for a residual roughening of the clavicle demonstrable on palpation. The patient was discharged as tentatively cured with instructions to return twice yearly for short courses of injections. At the time of publication, Christian and Palmer report the patient to be living, well and free from recurrence two years after the beginning of treatment.

The Coleys¹⁷ record the histories of fifty-five cases of sarcoma including photographs, roentgenograms, photomicrographs and complete follow-up records. Several of these patients had definite pulmonary or other distant metastases; in most cases the pathologic diagnosis was confirmed by such men as Caven of Toronto, Ewing of New York or Welch of Baltimore. These are the cases a statistical abstract of which was discussed in a previous paragraph.

It appears that (1) undoubtedly the combined toxins of erysipelas and prodigious may sometimes play a significant rôle in preventing or retarding malignant recurrence or metastasis; (2) occasionally they may be curative in hopelessly inoperable neoplasms; (3) probably their value is rather strictly

limited to tumors of entodermal or mesodermal derivation and, more particularly, in the case of bone tumors, to those exhibiting little or no osteoplasia. The Council has, for these reasons, retained Erysipelas and Prodigiosus Toxins-Coley in New and Nonofficial Remedies, with a view to facilitating further studies with the product, especially in connection with its use as a prophylactic in conjunction with conservative or radical surgery. Its use in definitely inoperable cases may be quite justified, in many instances, as a desperate attempt to combat the inevitable.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

RITTER TOMATO JUICE

Manufacturer.—P. J. Ritter Company, Philadelphia.

Description.—Canned tomato juice, retaining in high degree the natural minerals and vitamins. Seasoned with salt.

Manufacture.—Field ripened, selected tomatoes are washed in running water and by water sprays, inspected for removal of damaged and unsuitable fruit, trimmed by hand, again sprayed with water, passed through a steamer, automatically cut, and conveyed to a supply kettle which feeds a screw type, stainless steel air tight machine for expressing the juice through a fine screen. The juice is conveyed to stainless steel kettles and is heated to 85 C. in about six minutes, salt is added, and the juice is flowed through glass lined pipes to the filling machines and filled into bottles or enamel lined cans, which are processed at 90 C. and cooled to 37 C.

Analysis (submitted by manufacturer).—	per cent
Moisture	93.1
Total solids	6.9
Ash	1.2
Sodium chloride	0.8
Fat (ether extract)	0.1
Protein (N X 6.25)	1.0
Reducing sugars before and after inversion	3.5
Crude fiber	0.1
Carbohydrates other than crude fiber (by difference) ..	4.5

Calories.—0.2 per gram; 6 per ounce.

Claims of Manufacturer.—This tomato juice is prepared by a process permitting retention in high degree of its natural vitamins A, B and C.

KRIM-KO CHOCOLATE FLAVORED DRINK

Bottlers and Distributors.—(1) Chapman Dairy Company, Kansas City, Mo.; (2) Concordia Creamery Company, Concordia, Kan.; (3) Elmhurst Dairy, Inc., Hornell and Wellsville, N. Y.; (4) Fargo Dairy, Inc., Batavia, N. Y.; (5) Fischl Ice Cream and Dairy Company, Manitowoc, Wis.; (6) Geneva Milk Company, Geneva, N. Y.; (7) Graham Milk Company, Ottumwa, Iowa; (8) Hydrox Dairy, Inc., Olean, N. Y.; (9) Ionia Creamery Company, Inc., Ionia, Mich.; (10) Lehrack-Ferguson Dairy Products Company, Wichita Falls, Texas; (11) Lemke Milk Products Company, Wausau, Wis.; (12) Luce Dairy Company, Ithaca, N. Y.; (13) Magic City Ice and Milk Company, Endicott, N. Y.; (14) Merkle Dairy Company, Kalamazoo, Mich.; (15) Muller's Dairy, Rockford, Ill.; (16) Natoma Farm, Hinsdale, Ill.; (17) Quality Milk Company, Fort Smith, Ark.; (18) Sheboygan Dairy Products Company, Sheboygan, Wis.; (19) Sunlite Dairy Company, Oshkosh, Wis.; (20) Topeka Pure Milk Company, Topeka, Kan.; (21) The United Dairy Company, Wheeling, W. Va.; (22) Weber Dairy Company, Joliet, Ill.; (23) West End Dairy,

Charleston, S. C.; (24) Williamsport Milk Products Company, Inc., South Williamsport, Pa.

Licenser.—Krim-Ko Company, Chicago, manufactures the Krim-Ko Chocolate Flavored Drink Base and licenses its use, the name Krim-Ko, and standard advertising under definite contract conditions.

Description.—Pasteurized chocolate flavored sweetened skim milk; contains skim milk (from 0.5 to 1.5 per cent milk fat), sucrose, chocolate and cocoa, tapioca flour, salt and traces of tartaric acid and agar; flavored with imitation vanilla extract. See Krim-Ko Chocolate Flavored Drink, THE JOURNAL, June 30, 1934, page 2187.

VITAMIN D FORTIFIED PASTEURIZED MILK

- (1) AVONDALE FARMS
- (2) BROADVIEW DAIRY
- (3) QUALITY DAIRY PRODUCTS COMPANY
- (4) RIDER'S
- (5) SEFCIK DAIRY CO.'S
- (6) SOUTHERN DAIRIES
- (7) SPRINGBROOK DAIRY'S
- (8) VITEX LABORATORIES

Distributors.—(1) Avondale Farms Creamery, Inc., Knoxville, Tenn. (2) Broadview Dairy, Inc., Portland, Ore. (3) Quality Dairy Products Company, Salt Lake City. (4) The Rider Dairy Company, Danbury, Conn. (5) Sefcik Dairy Co., Chicago. (6) Southern Dairies, Inc., Asheville and Winston-Salem, N. C., and Knoxville, Tenn. (7) Springbrook Dairy, Portland, Ore. (8) Vitex Laboratories, Detroit.

Description.—Bottled pasteurized milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil); contains 400 U. S. P. X (Revised, 1934) vitamin D units per quart.

Preparation.—The milk complies with legal requirements and is pasteurized by the standard holding method. See THE JOURNAL, July 1, 1933, page 34, for description of fortification with vitamin D.

Vitamins.—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent, if the proper amount is used.

Claims of Distributors.—A vitamin D fortified, antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

DOLE HAWAIIAN FINEST QUALITY PINEAPPLE

DIAMOND HEAD BRAND CRUSHED, SLICES AND TIDBITS
HAWAIIAN CLUB BRAND CRUSHED, SLICES AND TIDBITS
HONEY DEW BRAND CRUSHED, SLICES AND TIDBITS
PANAMA PACIFIC BRAND CRUSHED AND HALF SLICES
PINE-HEART TIDBITS

SEA ISLAND BRAND SLICES AND HALF SLICES
SURF RIDER BRAND CRUSHED AND HALF SLICES

Packer.—Hawaiian Pineapple Company, Ltd., San Francisco.

Description.—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole Hawaiian canned pineapple products (THE JOURNAL, April 8, 1932, p. 1106, and April 29, 1933, p. 1338).

HIGH UP BRAND GOLDEN SYRUP

Distributor.—The Guymon-Petro Mercantile Co., Dodge City and Hutchinson, Kan.

Packer.—The Hubinger Company, Keokuk, Iowa.

Description.—Table syrup; corn syrup flavored with refiners' syrup. The same as Hubinger Golden Table Syrup, THE JOURNAL, January 20, 1934, page 213.

Claims of Manufacturer.—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

SATURDAY, OCTOBER 6, 1934

NURSING EDUCATION

Phenomenal advances in the science of medicine during half a century have been paralleled by significant improvement in the art of caring for the sick. The development of the trained nurse has been an influential factor. Physicians, therefore, are vitally interested in the proper integration of nursing in the practice of medicine. The final report of the Committee on the Grading of Nursing Schools, containing the results of a comprehensive study of nurse training and nurse practice conducted over a period of eight years, emphasizes the rapid increase in the production of trained nurses and the widespread unemployment that was manifest even before the onset of the period of economic depression. Most people will readily agree that one nurse for every 100 families is more than the country can be expected to support.

The surplus of nurses is due, in part at least, to the large number of poor or mediocre schools in which the educational function is subordinated to the financial exigencies of the hospital. Many of these should be closed just as rapidly as the hospitals can make other arrangements for caring for their patients. One half of all the schools of nursing in the United States are conducted by hospitals with not more than seventy-five patients, while one fourth of the hospitals have only from eight to forty-two patients. The report lays stress on the excellence of the university schools of nursing and on the need of liberal endowments to maintain schools of this type. It recommends that most of the training schools be closed and that hospitals employ graduate nurses rather than students in caring for their patients. In this way the idle could be reemployed and the quality of hospital service improved. Moreover, the prediction is made that the change can be effected without increasing costs.

The committee considers in detail plans for improving nursing schools but realizes that schools most needing improvement will be least likely to adopt its suggestions. It therefore raises the question whether schools of nursing should not be licensed. It recom-

mends that registration of graduate nurses be required in every state and studies made to determine whether all workers who take care of the sick for hire should be licensed. The failure to enforce medical practice acts should have indicated to the committee the likelihood that similar legislation for nurses would be inoperative.

In a summary of its investigations the committee says: "The present system of nursing education is, in general, not attracting as many women of adequate capacity and basic training as would be desirable and is not giving them the quality of training which fits them for the demands of their professional career. On the other hand, it is producing far too large a number of nurses of a type unsuited to those demands." Opinions as to the proper function of the nurse are so divergent that these conclusions will not meet with unquestioning assent.

ERYSIPELAS AND PRODIGIOSUS TOXINS (COLEY)

In this issue of THE JOURNAL (p. 1067) is reported the reacceptance for inclusion in New and Nonofficial Remedies of Erysipelas and Prodigiosus Toxins (Coley), long, albeit somewhat sporadically, employed in the treatment of selected cases of inoperable bone sarcoma. Although Coley first employed a vaccine of *Streptococcus erysipelatis* in inoperable malignant conditions as early as 1893, a satisfactory explanation of the therapeutic mechanism has not yet been advanced. The use of the product, like that of nonspecific proteins, has rested on an empirical basis supported solely by clinical observations of occasional cases of inoperable malignant disease which have exhibited spontaneous regression following fulminating attacks of acute infectious diseases, particularly erysipelas. Sir James Paget is said to have been the first to record such an occurrence.

Jacobsen¹ in a recent paper advances a theory based on related observations of the alleged increased incidence of cancer and the noteworthy present-day decrease of acute bacterial diseases in general. He cites a series of facts which, it is claimed, will represent the uniform observations of any selected group of widely experienced clinicians with reference to the incidence of malignant growths in patients the past victims of a common infectious process. Among his citations are the lessened frequency of neoplastic disease in the actively tuberculous, in the chronically osteomyelitic and in patients with acute infectious diseases in general, but particularly in those giving a history of typhoid, paratyphoid, scarlatina and diphtheria. Jacobsen's statement that remission of a malignant process following erysipelas is less likely to be permanent than that following typhoid or any acute process which produces a lasting, serologically demonstrable and specifi-

1. Jacobsen, C.: Chronic Irritation of Reticulo-Endothelial System Hindrance to Cancer, Arch. f. Dermat. u. Syph. 169: 562 (Feb.) 1934.

cally homologous immunity tend to controvert Coley's stand. The theory is put forth that the increased cancer rate, while due to modern public health and sanitary measures, is not a function of the increased number of persons now enabled to attain the so-called cancer age. To render this view tenable, the greater occurrence of cancer in the age group from 30 to 50 is cited.

Little experimental work is quoted, although Teutschlander² has demonstrated a definite decrease in the susceptibility of tuberculous fowls to the Rous chicken sarcoma.

Jacobsen concludes (1) that the evidence tends to support the hypothesis that the reticulo-endothelial system, when sufficiently active (as when stimulated by one or a number of acute infectious processes), may attain in a measure the ability to cope with neoplastic diseases in a similar if not identical manner, and (2) that the present increase in malignant morbidity is due to the decreased resistive powers of the reticulo-endothelial system occasioned by the lessened incidence of exposure to and infection of the general public with those diseases which were widely endemic before the advent of modern public health methods. As a corollary to these conclusions it is suggested that routine immunization of cancerous patients to typhoid up to an agglutinin titer of 1:800 may prove of value but that surgery should remain the therapeutic measure of choice whenever conditions permit. Two of the conclusions would appear too broad in the light of the reported evidence; namely, (1) that as acromegaly is regarded as a disease of the pituitary so should cancer be regarded as a disease of the reticulo-endothelial system, and (2) that the hope of prevention, if not the treatment of cancer, lies in vaccinotherapy with markedly antigenic substances. The possibility of accumulating more accurate data in this regard seems particularly likely at present through a follow up and study of the cancer rate among veterans of the World War, the vast majority of whom were subjected to typhoid-paratyphoid inoculation.

These observations, in the main, are dependent on statistical surveys; it is only reasonable to point out that the matter of the trend of cancer incidence is distinctly controversial at present. If Wood's³ views or those recently expressed editorially by THE JOURNAL⁴ are correct, Jacobsen's work is untenable. However, if Macklin's⁵ report is reliable, Jacobsen's reticulo-endothelial theory is deserving of thoughtful consideration.

Whatever the immediate decision, it would appear possible that public health and sanitation, as developed throughout the years, may prove to have been a two-edged sword. Certain it is, however, that its sharpest

edge, thus far, has been that which has reduced typhoid, plague, cholera, smallpox, diphtheria and a score of other diseases to the realm of the infrequent and added years to life expectancy in comparison with which even the increased cancer toll seems of significantly lesser importance. Further studies on the effect of powerfully antigenic substances in inoperable malignant conditions or as a postoperative measure in attempting to combat recurrence seem to be indicated in the light of the accumulated evidence.

REBATES AND COMMISSIONS

Elsewhere in this issue (p. 1088) appears a letter from the secretary of the American Surgical Trade Association discussing the code under which dealers in surgical apparatus and supplies will work under the National Recovery Act. The significant paragraph for physicians is one that now places legal control over a situation that was formerly subject only to ethical considerations.

For many years the organized medical profession of this country has been opposed to the acceptance of commissions or rebates by doctors from the manufacturers of surgical supplies. The practice is a low form of the division of fees. It is developed primarily to induce doctors to send their patients to manufacturers who pay large commissions rather than to those able to supply the patient with the apparatus required at the lowest possible cost. Many physicians of high principles adopted the practice of turning over such rebate checks directly to their patients; others simply returned the checks to the manufacturer and discontinued the recommendation of patients to such manufacturers. Others, however, accepted such fees, consoling themselves with the thought that the fee might be considered an added honorarium for determining that the apparatus fitted the condition for which it was prescribed. Nevertheless, reasonable excuse is not to be found for this practice. In its eventual effects on the patient and on the practice of medicine it could do nothing but harm. Hence, regardless of what one may think personally of the development of the codes and of their application to industry, the legal restriction on the giving of rebates is bound to have a beneficial effect on this phase of medical practice.

In certain other ways, as well, the codes are beginning to operate for the development of higher standards in relationship to other phases of medical work. It seems likely that the use of the word "doctor" in commerce for promoting the sale of various types of shoes or other goods will also be restricted to legitimate purposes. In the drug field, higher standards are being developed for several phases of the industry.

In other branches of commercial life, some manufacturers have already found means for evading the spirit of the codes to which they affixed their signatures. The medical profession, with many centuries of ethical

tradition behind it, will welcome these new forms of control, which place the force of the law behind the principles of right that the profession has always recognized and, for the most part, observed.

THE COURTS AND THE MILK SUPPLY

Cooperation between various governmental bureaus with appreciation of special points of view leads to efficient service for the public. This situation has come to pass between the judiciary and those groups whose concern is the public health with relation to milk control. Tobey¹ has stated that the "sagacious principles set forth by the learned judges will appeal to the dairy industry because of the recognition accorded the nutritional value of milk; and these decisions will likewise find favor with health officials because of the liberality with which all reasonable regulation of milk in the interests of public health and welfare is upheld." In the past thirty years or more several important decisions relative to milk control have been rendered by the federal Supreme Court. These decisions concerned, among others, the state's power to delegate to local health authorities the supervision of milk control, to regulate the sanitary production of milk and to prohibit impure milk or diseased cattle from entering a state. However, the recent decision upholding an emergency law of New York is by far the broadest yet handed down. Thus the court contends that price fixing under certain restrictions is a proper use of the police power of the state to regulate the "health, safety, comfort, morals and welfare of the people."

Numerous court decisions have declared that laws leading up to the eradication of bovine tuberculosis are constitutional. In 1932 the Supreme Court of Minnesota ruled that county commissioners have discretionary power to provide for tuberculin testing and that they must do so when petitioned, as these boards are agencies of the state in carrying out "its own paramount governmental duty to protect public health." The first decision on record dealing with public health measures for the control of undulant fever was rendered by the United States Supreme Court in 1933. A state commissioner of agriculture and markets denied entry of a herd of cattle on the ground of failure to possess a certificate showing freedom from Bang's disease, the cause of undulant fever in man; this order was subsequently upheld by the higher court on the ground that it was rendered in good faith and to safeguard public health by preventing the spread of the disease among cattle.

The purchase of milk bottles is an item of no inconsiderable expense in the distribution of milk. An ordinance in a Southern city required that milk bottles bear no other name or trade mark than that of the producer or distributor. The Supreme Court decided that this requirement was unreasonable and would, if

enforced, prevent even the name of the manufacturer on the bottle. The decision, however, left no doubt as to the recognition by the court of the importance of a sanitary milk supply and of the right of the government to enforce necessary regulatory measures. The stress of business conditions leads constantly to efforts to circumvent the dicta of safe practices in the production, processing and distribution of milk; it is a comfort to be assured that the higher tribunals acknowledge the significance of a sanitary supply of this essential food.

Current Comment

INTENSIVE TREATMENT OF DEMENTIA PARALYTICA

The clinical picture of dementia paralytica of thirty years ago seems to be losing some of its easily recognizable features. The expansive, euphoric psychosis or the pronounced neurologic symptoms that formerly were so common are not now so frequently observed. This change may be due to the fact that the present group of patients in the early period of their syphilitic infection were treated with such effective remedies as arsphenamine and other modern arsenicals. The patient today may show behavior changes without pronounced psychoses and at the same time laboratory changes indicative of cerebral invasion by the spirochetes. Carlisle and O'Neil¹ have reported ninety-nine cases of dementia paralytica, all of which presented behavior disorders and the usual neurologic and laboratory signs. These patients, mostly world war veterans, were followed up month after month for a long period, during which the changes in the clinical and laboratory observations were carefully noted. The patients were treated to the utmost. One patient, for example, in about four years received 186 injections of tryparsamide, 182 injections of bismuth compounds, 56 injections of sulpharsphenamine and 44 injections of mercury compounds. Many of them were also given malaria therapy. One patient was subjected to 17 malarial chills, 132 injections of tryparsamide, 134 injections of bismuth compounds, 44 injections of mercury compounds and 39 injections of sulpharsphenamine. In fact, the authors designate their treatment of these cases as "extra-intensive treatment." Sixteen of these patients have thus been enabled to leave the hospital and they have been making a satisfactory adjustment. Of those remaining in the hospital, 85 per cent have parole and pass privileges. The majority have been permitted to visit outside the hospital ninety days or more and there were no conflicts. Four of the patients have died. The authors believe that the agitative type of patient reacted more favorably to malaria therapy. Some cases have shown improvement, while their serologic reactions continued strongly positive; others have shown no mental improvement, while their serologic reactions continued to be negative. Nine of these cases have shown no mental improvement under "extra-intensive treatment."

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be as follows:

- October 11. Multiple Births, W. W. Bauer, M.D.
- October 18. Keep Fighting Diphtheria, W. W. Bauer, M.D.
- October 25. What Is a Serum? W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

- October 9. School Health Problems, W. W. Bauer, M.D.
- October 16. Research in Medicine, A. C. Ivy, M.D.
- October 23. Reading About Health, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal.—Dr. William J. Donald, Athens, for several years health officer of Limestone County, has been appointed in charge of the health unit of Covington County, with headquarters in Andalusia.—Mr. W. Thurber Fales, Montgomery, for ten years director of the bureau of vital statistics of the state department of health, has resigned to accept a similar position with the Baltimore health department.

Protest Publicity on Dengue Fever.—The Etowah County Medical Society has adopted a resolution protesting against the publicity given to the prevalence of dengue fever in the county. Declaring that this publicity might prove harmful, especially since no case had been reported in twenty-five years, the society called on the state health department to give, through the press, the full facts regarding the prevalence of the disease. Newspapers pointed out that the county had been selected with others in the state as a site for the campaign against the disease to prevent its introduction from adjacent states where outbreaks have been reported. The resolution commended the state and local health departments for their efforts to eradicate mosquitoes.

ARKANSAS

Clinical Conference.—The staffs of the Leo N. Levi Memorial Hospital and the Charles Steinberg Clinic will hold their fourth clinical conference, Hot Springs National Park, October 11. Guest speakers will be Drs. George R. Livermore, professor of urology, University of Tennessee School of Medicine, Memphis, and Col. William B. Meister, chief of the medical service, Army and Navy General Hospital, Hot Springs National Park. The conference will consist of lectures, demonstrations and clinics on medical and surgical subjects of especial interest to the general practitioner. Instead of reading papers this year, members of the staff will present cases and clinical reports. The meeting will close with an informal dinner at the Arlington Hotel. No registration fee will be charged.

CALIFORNIA

New Department of Bacteriology.—A department of bacteriology has recently been established at the University of California at Los Angeles, according to *Science*. Carl C. Lindgren, Ph.D., research assistant in microbiology at the Mellon Institute, Pittsburgh, has been appointed chairman.

Jailed for Violation of Medical Practice Act.—William Fisher, Los Angeles, was sentenced to jail for 180 days following his plea of guilty to a charge of violating the medical practice act. He was committed to jail when he was unable

to pay a fine of \$600. Fisher used an escharotic cancer paste, with which he is said to have treated a patient for cancer of the breast for several months.

Personal.—Dr. Dorothy M. Henderson, Van Hornesville, N. Y., has been appointed medical adviser to women and director of women's physical education at Stanford University, succeeding Dr. Bertha Sabin Stuart Dymont, it is reported. Dr. Henderson is a graduate of Northwestern University Medical School, Chicago, class of 1932.—Dr. Francis M. Stump, Crescent City, has been appointed health officer of Del Norte County to succeed Dr. William J. Stump.—Dr. Warren L. Nichols has succeeded Dr. Donald C. Fowler as city health officer of Exeter.

Society News.—Dr. Arthur Elmer Belt, Los Angeles, addressed the Galen Medical Society in San Diego, September 10, on "Obstructive Uropathy." The Galen society is composed of younger members of the San Diego County Medical Society.—Dr. Leo L. Stanley, San Rafael, addressed the Hollywood Academy of Medicine, September 20, on "Looking Back on Twenty Years of Prison Medicine."—Dr. James C. Hayes, Medford, Ore., addressed the Humboldt County Medical Society in Crescent City, August 16, on "Fractures of the Long Bones," and Dr. George K. Rhodes, San Francisco, "Drainage of the Abdomen and Traumatic Injuries to the Abdomen."—Dr. Joseph Salem Rubin, Los Angeles, addressed the Imperial County Medical Society in Calexico, September 18, on "Nephroposis."

DELAWARE

Health at Wilmington.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 22, indicate that the highest mortality rate (19.1) appears for Wilmington, and the rate for the group of cities as a whole, 9.6. The mortality rate for Wilmington for the corresponding period last year was 11.3, and for the group of cities, 9.8. The annual rate for eighty-six cities for the thirty-eight weeks of 1934 was 11.4, as compared with 10.9 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

DISTRICT OF COLUMBIA

University News.—New appointments at George Washington University School of Medicine include that of Dr. Herbert P. Ramsey as assistant professor of obstetrics and gynecology. Among the guests present at the opening of the one hundred and tenth academic year were Dr. John L. Reenstierna, professor of bacteriology, University of Upsala, Sweden.

Personal.—Brig. Gen. Frank R. Keefer, U. S. Army, retired, formerly assistant surgeon general, was recently awarded the honorary degree of doctor of science by Dickinson College, Carlisle, Pa.—Lieut. Col. Jules Voncken, director of the Military Hospital at Liège, was guest of honor at a luncheon at the Army and Navy Club, September 6. Colonel Voncken was en route to Tokyo to represent Belgium at the International Conference of Red Cross Societies.

FLORIDA

Society News.—At a recent meeting of the Bay County Medical Society in Panama City, Dr. James M. Hoffman, Pensacola, directed a symposium on cancer control. Other speakers on the program included Drs. Mozart A. Lischkoff, Pensacola, on common ear conditions; John T. Ellis, Dothan, hematuria, and James H. Fellows, Pensacola, location of hemorrhage in brain due to birth injuries.—Speakers before the Dade County Medical Society, September 7, were Drs. Robert T. Spicer, Miami, on trichomonas vaginalis, and Ernest Donald, Miami, the rectum.

GEORGIA

Triple Vaccine Discontinued.—The laboratory of the Georgia State Department of Health has discontinued the distribution of mixed or typhoid-paratyphoid vaccine. The facts that paratyphoid fever is relatively rare in Georgia and that the U. S. Army, which first introduced the use of triple or mixed typhoid vaccine, has recently discontinued its use entirely were cited as reasons for this action.

Personal.—Dr. Isaac C. Evans has been named city physician and health officer of Columbus, succeeding Dr. William E. Mayher Jr., resigned.—Dr. H. P. Rankin, formerly of Elba, Ala., has been appointed health officer of Grady County

to succeed Dr. James R. Dykes; the latter has been named to a similar position with the Thomas County Health Department, with headquarters at Thomasville, succeeding Dr. Hugh B. Jenkins, who resigned to become medical inspector for the Civilian Conservation Corps at Pensacola, Fla.—Dr. Emile B. Woods, Valley Junction, Iowa, has been appointed assistant professor of obstetrics and gynecology, University of Georgia School of Medicine, Augusta.

District Meeting.—The Fifth District Medical Society will meet at the Academy of Medicine, Atlanta, October 18. Dr. Marion C. Pruitt, Atlanta, president of the Fulton County Medical Society, will give the address of welcome, and Dr. Clarence L. Ayers, Toccoa, president, Medical Association of Georgia, the response. Other speakers on the program will include:

Dr. William F. Shallenberger, Atlanta, Surgical Complications of Pregnancy.

Dr. James E. Paullin, Atlanta, Pathology of Rheumatoid and Hypertrophic Arthritis.

Dr. Tinsley R. Harrison, Nashville, Pathogenesis of Congestive Heart Failure.

Dr. Isidore Cohn, New Orleans, Masses in the Groin.

Dr. Joseph Yampolsky, Atlanta, is president of the district society, and Dr. Hulett H. Askew, Atlanta, secretary.

ILLINOIS

Health Survey of Negro Children.—That the Negro children under preschool age in East St. Louis are in good physical condition is indicated in a recent survey made by the state department of health. This condition prevails despite the fact that nearly one half of them are in families on relief, it was stated. Only 117 out of 715 children examined exhibited any degree of deviation from normal nutrition. Nearly three fourths, or 72 per cent, had no decay whatever in their teeth. Only seventeen had detectable visual defects and only fifteen had any impairment of hearing. There were twenty-four with some manifestation of heart impairment or abnormality. The survey was carried on during the first week in September to determine prevailing health conditions among Negro children with a view toward establishing a program for the improvement of the race (*THE JOURNAL*, September 1, p. 686). The study was made in St. Clair County where the Negro population is principally concentrated.

Chicago

Personal.—Dr. Frank S. Needham, Oak Park, won the Van Derslic cup at the annual golf tournament of the Chicago Medical Society, August 1, with a low gross score of 79.—A tea was given by friends of the late Dr. Charles H. Miller, September 20, as a part of a campaign to raise funds for the Charles H. Miller Memorial Fund, which will be used to endow a room at the Woodlawn Hospital. Dr. Miller died last March.

Course for Pediatricians.—The management of children's behavior problems is the theme of a series of lectures to be given at the Institute for Juvenile Research, 907 South Lincoln Street, under the auspices of the University of Illinois College of Medicine. Lectures will be delivered on Tuesdays, October 9 to November 27. For a limited number of physicians these lectures may be supplemented by clinical experience in the treatment of children's behavior problems under supervision. Dr. Paul L. Schroeder is director of the Institute of Juvenile Research.

Symposium on Cancer.—Carcinoma of the breast will be considered in a symposium before the Chicago Medical Society, October 10. Dr. William C. MacCarty, professor of pathology, University of Minnesota Graduate School of Medicine, Rochester, will discuss the pathology; Dr. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, the diagnosis and differential diagnosis; Dr. Arthur D. Bevan, clinical professor of surgery, Rush Medical College, surgical treatment, and Dr. Edward L. Jenkinson, roentgenologist of St. Luke's Hospital, the radiologic treatment.

Discussion of Medical Practice and Economics.—Medical practice and government plans for economic security will be discussed at a meeting of the North Side Branch of the Chicago Medical Society in Thorne Hall, McKinlock Campus, Northwestern University School of Medicine, October 8. Participating in the symposium will be the following:

Dr. Olin West, Secretary and General Manager, American Medical Association, The Situation Today.

Dr. Roscoe G. Leland, Director, Bureau of medical economics, American Medical Association, What Medicine Is Doing.

Dr. Morris Fishbein, Editor, *THE JOURNAL* of the American Medical Association, What Medicine Should Do.

Frederick A. Britten, congressman, ninth district, The Legislator's Viewpoint.

Guests of honor at this meeting will include Drs. Charles H. Phifer, Julius H. Hess and Thomas P. Foley, president, president-elect and secretary of the Chicago Medical Society, respectively; Stanley D. Tylman, D.D.S., president of the Chicago Dental Society; George L. Secord, president, Chicago Retail Druggists Association, and Lenore Tobins, president of the first district, Illinois State Nurses' Association. Members of these organizations are requested to bring interested friends. Dr. Irving S. Cutter, dean, Northwestern University School of Medicine, will give the address of welcome.

INDIANA

Society News.—Dr. Harry E. Mock, Chicago, will speak before the Tippecanoc County Medical Society in Lafayette, October 16, on "Management of Acute Head Injuries." Dr. Jean P. Pratt, Detroit, discussed "Endocrine Disturbances Peculiar to Women," September 13.—Dr. Claud R. G. Forrester, Chicago, will speak before the Tenth District Medical Society in Gary, October 31, on "Reduction of Fractures Under Local Anesthesia with Ambulatory Treatment."

IOWA

Society News.—A symposium on cancer of the stomach was presented before the Des Moines Academy of Medicine and Polk County Medical Society, September 25, with the following speakers: Drs. John T. Strawn, William E. Sanders and John B. Synhorst. Dr. Clinton E. Harris, Woodmen, Colo., will speak before the organization, October 8, on "Diagnosis of Lung Tumors," and Dr. Russell L. Cecil, New York, October 26, "Influenza and the Common Cold."—Speakers before the Dubuque County Medical Society, September 11, included Drs. Porter P. Vinson, Rochester, Minn., on "Bronchoscopic Diagnosis and Treatment of Lung Conditions"; Frederick A. Figi, Rochester, Minn., "Fractures of Nose, Jaws and Other Facial Bones," and Leo G. Rigler, St. Paul, "Early Diagnosis of Cancer."

KENTUCKY

Health Officer Appointed.—Dr. Charles W. Garrison, Little Rock, Ark., formerly state health officer of Arkansas, has been appointed health officer of Lexington to succeed Dr. Garland L. Weidner, who resigned a year ago. Dr. Garrison served as head of the health service of Arkansas from 1914 to 1933. He is a former president of the Conference on State and Provincial Health Authorities of North America and in 1924 represented the United States at a League of Nations Health Conference in Geneva.

Society News.—Dr. James W. Bruce, Louisville, addressed the Jefferson County Medical Society, September 17, on "Treatment of Burns in Children." Dr. Joshua B. Lukins, Louisville, addressed the society, September 3, on malpractice suits.—Drs. Isaac A. Arnold and John T. Bate Jr. addressed the Louisville Surgical Society, September 27, on "Gas Gangrene" and "Injuries of the Supraspinatus Muscle," respectively.—Dr. Claude S. Eddleman was the speaker at a meeting of the Louisville Urological Society, September 25, on "Calculi of the Upper Urinary Tract."

LOUISIANA

Society News.—At a meeting of the Bi-Parish Medical Society (East and West Feliciana parishes) in Jackson, recently, Drs. Charles H. Voss and Irvine Ashton Robins, Baton Rouge, discussed "Diseases of China" and "Treatment for Primary Syphilis."—Dr. Fred W. Rankin, Lexington, Ky., addressed the Shreveport Medical Society, September 8, on cancer of the intestine.

Tri-State Meeting.—The Tri-State Medical Society of Arkansas, Louisiana and Texas will hold its annual session in Shreveport, October 16-17. Included among the speakers will be the following physicians:

Theodore M. Oxford, Shreveport, Fracture and Dislocation in the Elbow Region.

Wyeth B. Worley, Shreveport, Pyelitis in Children.

Arthur C. Scott, Temple, Texas, Gallbladder Surgery.

Ernest Sachs, St. Louis, Diagnosis and Treatment of Trigeminal Neuralgia.

Marvin T. Green, Ruston, Acute Suppurative Parotitis as a Complication in Abdominal Surgery.

Barton A. Rhinehart, Little Rock, Modern Gastro-Enterology.

Dr. Vesse R. Hurst, Longview, Texas, will give his presidential address on the opening morning. Other speakers will include the mayor, George W. Hardy; Dr. William S. Kerlin, president, Shreveport Medical Society, and Leonce J. Kosminsky, Texarkana.

MASSACHUSETTS

Public Relations Committee.—The Middlesex South District Medical Society has appointed a committee to study and promote better relations between the medical profession and the public. Dr. David C. Dow, Cambridge, has been named chairman of the committee which includes as members Drs. Elmer W. Barron, Boston; Charles F. K. Bean, Medford; Fred A. Higginbotham, Watertown; Walter H. Crosby, Boston; Dana F. Cummings, Natick, and Norman M. Hunter, Hudson. The report stated that the newly formed committee will work with Dr. Charles E. Mongan, Somerville, who is a member of the House of Delegates of the American Medical Association.

MINNESOTA

Credit Bureau Formed.—Twenty-four physicians of Winona County recently formed the Winona County Physicians' Credit Bureau. A credit list of all patients who have made no payments on accounts for six months is being compiled. Emergency service to relief patients is not included.

Chiropractor Sentenced for Producing Abortion.—Mrs. Katie Mac Jenks, a licensed chiropractor, pleaded guilty to a charge of criminal abortion in the district court at Alexandria, July 25, and was sentenced to two years at hard labor in the Women's Reformatory at Shakopee; she began her sentence, July 30.

Tuberculin Testing of Cattle.—Seventy-four of the eighty-seven counties in Minnesota are now accredited in accordance with regulations governing the tuberculin testing of cattle with the incidence of tuberculosis 0.5 per cent or less. It is expected that seven other counties will be accredited by the end of October, although it will be impossible to accredit the remaining six counties before June 1935. It was pointed out that the first tuberculin test has been administered to all the cattle in the state. The work has been somewhat handicapped by the drought, which made it impossible to adhere strictly to quarantine provisions in some accredited counties, because large numbers of cattle from drought-stricken counties were moved there for sustenance, according to the *Journal-Lancet*.

MISSOURI

Art in Medicine.—The William Rockhill Nelson Gallery of Art will be the scene of a special program planned by the entertainment committee of the Kansas City Southwest Clinical Society for registrants at the fall clinical conference. Mr. Paul Gardner, director, will discuss "Masterpieces of the Gallery Collection"; Dr. Logan Clendening, Kansas City, "Medical Subjects in Classic Art," and Dr. Edward H. Skinner, Kansas City, "Art and X-Ray."

Society News.—At a meeting of the Jackson County Medical Society in Kansas City, September 11, Drs. Carl H. B. Schutz and Ferdinand C. Helwig discussed water intoxication, and Dr. Cecil M. Kohn, "Treatment of Cardiac Disease by Total Thyroidectomy."—The Nodaway County Medical Society was addressed in Maryville, September 5, by Drs. James G. Montgomery and Donald R. Black, Kansas City, on "Surgery of the Spleen" and "Treatment of Diabetes," respectively.

Survey of After Effects of Encephalitis.—To determine the after effects of encephalitis, a survey was undertaken in St. Louis and St. Louis County the latter part of September by the St. Louis Metropolitan Health Council. The council has asked private physicians for permission to examine their patients with a view to reaching all patients still residing in the city and county. The work is expected to take three months and it is planned now to repeat the survey in a year. Official records show 1,097 cases of encephalitis with 221 deaths. Dr. Paul J. Zentay, St. Louis, is secretary of the Metropolitan Health Council.

NEW YORK

District Meetings.—The twenty-eighth annual meeting of the fourth district branch of the Medical Society of the State of New York was held in Gloversville, September 21-22. Among speakers were Drs. Edward M. Livingston, New York, on "Clinical Diagnosis of Surgical Diseases of the Abdomen"; Richard B. Cattell, Boston, "Diseases of the Colon," and Herman O. Mosenthal, New York, "The Heart Muscle with Advancing Years." At a dinner at the Sir William Johnson Country Club, speakers were Drs. Arthur J. Bedell, president, Medical Society of the State of New York, and Thomas

Parran Jr., state health officer, both of Albany.—Dr. Earl D. Osborne, Buffalo, was guest speaker at the annual meeting of the third district branch of the Medical Society of the State of New York at Livingston, September 19, on "Treatment and Prognosis of Early Syphilis." Dr. Arthur J. Bedell, Albany, president of the state medical society, also made an address.—At the annual meeting of the sixth district branch of the Medical Society of the State of New York in Cortland, September 26, speakers included Drs. Russell L. Cecil, New York, on "Treatment of Pneumonia"; Claude F. Dixon, Rochester, Minn., "Surgical Management of Carcinoma of the Rectum and Rectosigmoid," and Donald Guthrie, Sayre, Pa., "The Tragedy of Appendicitis." Dr. Arthur J. Bedell, Albany, president of the state society, discussed the *New York State Journal of Medicine*.—At the annual meeting of the seventh district branch of the Medical Society of the State of New York in Auburn, September 27, speakers included Drs. Russell L. Cecil, New York, on "Common and Unusual Heart Lesions," and Harrison S. Martland, Newark, N. J., "Management of Gastric Lesions, Peptic Ulcer and Malignancy."

Cornerstone for Saratoga Spa Laboratory.—A new unit of the spa being developed by the state at Saratoga Springs was started September 14, when the cornerstone was laid for the Simon Baruch Research Laboratory. Gov. Herbert H. Lehman presided at the ceremonies, naming the laboratory for Dr. Simon Baruch, a pioneer in hydrotherapy in this country and for many years professor of hydrotherapy at the College of Physicians and Surgeons, New York. His son, Dr. Herman B. Baruch, New York, laid the stone. Dr. John H. Wyckoff, dean, New York University—Bellevue Hospital Medical College, was the orator of the occasion. The laboratory building will be the largest in floor area of the group of buildings now under construction at Saratoga. It will contain physicians' offices, experimental rooms for baths and an auditorium in addition to laboratories for roentgenography, fluoroscopy, capillary examinations, blood pressure and basal metabolism determinations, chemistry and physics. Other buildings of the center will include the Hall of Springs, a bath house of distinctive design, a hotel with sanatorium facilities, a bottling plant for the spring waters, and a recreation center, at which the remedial uses of sports will be stressed. Dr. Walter S. McClellan is medical director of the spa and members of the Saratoga Springs Commission are Pierrepont B. Noyes, Oneida, chairman, and Drs. Carl R. Comstock, Saratoga Springs, and Lemuel Whittington Gorham, Albany.

New York City

Hospital News.—At the invitation of the Bronx Hospital, Dr. Erwin Schiff, former professor of pediatrics, University of Berlin, delivered three lectures at the hospital, September 14, 18 and 21, on "Dehydration and Intoxication," "New Points of View in the Treatment of Intoxication and Diarrhea in Infants," and "Therapy of Neurodermatitis in Infants."

City Hospital Capacity Taxed.—During the first six months of 1934 New York City hospitals operated at more than their normal capacity, according to a report of the department of hospitals issued recently. The average daily census for all institutions was 19,060, while the bed capacity averaged 18,463. The number of days of hospital care for the six months was 3,500,000, a rate of 7,000,000 days of care per year, or approximately one day of institutional care for each inhabitant of the city. In addition the city pays for about 1,000,000 days of care for indigent persons in 105 private hospitals. During the first six months of this year there were 8,483 births in the city's hospitals and 9,759 deaths. The mortality rate, based on the number of persons treated was 7.3. In twelve general hospitals, the average length of stay was sixteen days. In twelve special hospitals, which include hospitals for chronic nervous disorders, cancer, tuberculosis and communicable diseases, the average stay was sixty-seven days. The city operates 121 ambulances on general emergency calls and nine exclusively on contagious disease calls. In the year 1933, ambulances responded to 310,255 emergency calls; 166,698 patients were treated on the spot and not moved to hospitals. In 7,651 cases the patients were found dead on arrival of the ambulance.

Society News.—A symposium on acute anterior poliomyelitis will be presented before the section of neurology and psychiatry of the New York Academy of Medicine, October 9; speakers will be Drs. John R. Paul and James D. Trask, New Haven, Conn., Arthur R. Elvidge, Montreal, Maurice Brodie, William H. Park and Claus W. Jungeblut.—The council of the Physicians Equity Association of America, Inc., at a meet-

ing in New York, September 19, unanimously endorsed the ten principles of policy adopted by the House of Delegates of the American Medical Association at its June meeting in Cleveland. Members of the council are Drs. William M. Cooper, Joseph E. Conroy, Cassius L. De Victoria, Joseph J. Eller, Judson C. Fisher, Seymour Fiske, Charles Goodman, Harold M. Hays, Samuel M. Kaufman, Locke L. MacKenzie, Malcolm Campbell, Alexander Nicoll, Herman B. Philips, Joseph Safian, Herman Sharlit, Clarence H. Smith, Robert E. Walsh, Andrew A. Eggston and Edward R. Cuniffe.—The third annual meeting of the Society for Plastic and Reparative Surgery will be held in New York, October 9-12.—A symposium on arthritis will be presented at the meeting of the New York City branch of the Society of American Bacteriologists, October 9, by Dr. Reginald Burbank, Dr. Currier McEwen, H. R. Sinay, William Reiner-Deutsch, Ph.D., Dr. Maximin D. Touart, Dr. Martin H. Dawson, G. H. Chapman and Dr. William B. Rawls.—Dr. Harrison S. Martland, Newark, N. J., Dr. Thomas A. Gonzales and Alexander O. Gettler, Ph.D., will discuss "Scientific Crime Detection" before the Science Forum of the New York Electrical Society, October 17.

NORTH CAROLINA

Society News.—At a meeting of the Ninth District Medical Society in Statesville, September 27, speakers included Drs. George M. Cooper, Raleigh, on "Maternal and Infant Mortality in North Carolina," and Benjamin W. McKenzie, Salisbury, "Serum Proteins in Infections"; H. Calvin Rea, D.V.M., Charlotte, "Relationship of Animal Diseases to Human Health," and Ernest A. Branch, D.D.S., Raleigh, "Undernourishment as Reflected in the Mouth."—The Catawba Valley Medical Society met at Hickory, September 11, with the following speakers: Drs. William G. Bandy, Lincolnton, on "Coronary Thrombosis"; Walter V. Costner, Lincolnton, "The Normal Heart in the Child"; John S. Lewis, Hickory, "Differential Diagnosis Between Certain Heart Conditions and Certain Surgical Conditions," and Clyde R. Hedrick, Lenoir, "Practical Value of Electrocardiography."

OREGON

Professor of Biochemistry Appointed.—Edward S. West, Ph.D., since 1923 a member of the faculty of Washington University Medical School, St. Louis, has been appointed professor of biochemistry at the University of Oregon Medical School to succeed the late Dr. Howard D. Haskins. Dr. West has done extensive research in biochemistry, especially in the field of carbohydrates.

PENNSYLVANIA

Organization to Consider Public Health Legislation.—The public health committee of the Medical Society of the State of Pennsylvania has recently completed the organization of the Public Health Legislative Conference of Pennsylvania, whose purpose is the dissemination of evidence against legislation detrimental to public health and arguments for legislation favoring public health. The conference is made up of two representatives each of the state medical society, the state eclectic medical society, the state homeopathic medical society, the nurses' association, pharmaceutical society, dental society, hospital conference and the woman's auxiliary of the state medical society. Dr. Chauncey L. Palmer, Pittsburgh, is chairman, and Will D. Everhard, D.D.S., Harrisburg, secretary. Analogous organizations have been established in every county in which they are practical.

Philadelphia

Dr. Kolmer Resigns as Professor of Medicine.—Dr. John A. Kolmer has resigned as professor of medicine at Temple University School of Medicine to devote more time to research. He will continue to teach immunology, bacteriology and chemotherapy but asked to be relieved of clinical work. Dr. Kolmer has held the professorship of medicine at Temple since August 1932, having previously been professor of pathology and bacteriology at the Graduate School of the University of Pennsylvania. Since 1912 he has been head of the department of pathology of the Research Institute of Cutaneous Medicine and was recently made director and president of the board of trustees.

Airplane Survey of Pollen.—The Philadelphia College of Pharmacy and Science has launched an aerial survey of air-borne pollens, to be carried on for five years over the metropolitan area of Philadelphia, the New Jersey coast and out to sea for twenty miles. It is planned to measure accurately

the density, nature and distribution of air-borne pollen in the upper atmosphere. Daily flights will be made during the remainder of the current season and throughout the seasons for the next four years. At a special meeting marking the beginning of the project, Drs. Theodore B. Appel, state health officer, J. Norman Henry, director of health of Philadelphia, Randle C. Rosenberger, chairman of the air hygiene committee of Philadelphia, and Arthur C. Morgan made addresses.

Pittsburgh

Executive Secretary Resigns.—Mr. Lester H. Perry, executive secretary of the Allegheny County Medical Society since September 1931, has resigned to become managing editor of the *Pennsylvania Medical Journal* and manager of the annual sessions of the Medical Society of the State of Pennsylvania.

Practical Courses for Physicians.—The eighth series of practical courses sponsored by the Allegheny County Medical Society will begin in October. Subjects to be treated are the dietetic management of metabolic disorders, obstetrics, fundamentals of everyday dermatology, slit lamp microscopy and ophthalmoscopy, hyperthyroidism and hypothyroidism, acute neurologic conditions, medical emergencies, and orthopedic surgery for the general practitioner.

Branch Society Has Graduate Assembly.—The fourth annual graduate assembly of the Allegheny Valley Branch of the Allegheny County Medical Society was held, September 15, at Tarentum. An operative clinic was held in the morning at the Allegheny Valley Hospital and the following program of addresses was presented in the afternoon:

- Dr. William W. G. MacLachlan, Pittsburgh, Prognosis and Treatment of Pneumonia.
- Dr. John Alexander, Ann Arbor, Mich., Advancing Scope of Thoracic Surgery.
- Dr. Charles Howard Marey, Pittsburgh, Diagnosis and Treatment of Chronic Lung Infections.
- Dr. George W. Grier, Pittsburgh, Foreign Bodies in the Air Passages.
- Dr. Carey P. McCord, Cincinnati, Chest Diseases Caused by Dust.

VERMONT

Surgical Meeting in Burlington.—The annual meeting of the New England Surgical Society was held in Burlington, September 28-29. Among physicians who appeared on the program were:

- Dr. George A. Moore, Brockton, Mass., Bleeding Gastric Ulcer.
- Dr. Thomas N. Hepburn, Hartford, Conn., Ureterorectal Anastomosis.
- Dr. John Homans, Boston, Recurrent Peripheral Thrombophlebitis Causing Pulmonary Embolism.
- Dr. Richard H. Miller, Boston, Acute Hematogenous Osteomyelitis.
- Dr. Isaac M. Webster, Portland, Maine, The Limitations of Enterostomy and Undesirable Effects Incident to Its Use.
- Dr. James W. Sever, Boston, Slipping Epiphysis of the Head of the Femur.

GENERAL

Science Writers Form Association.—Announcement was made September 14 of the formation of the National Association of Science Writers, made up of staff members of newspapers and press associations who devote their major efforts to the field of science. Mr. David Dietz, Cleveland, science editor for the Scripps-Howard newspapers, is president of the association, the purpose of which is to "foster the dissemination of accurate scientific knowledge by the press of the nation in cooperation with scientific organizations and individual scientists."

Society News.—A special committee on the revision of the U. S. Pharmacopeia and National Formulary has been appointed to represent the American Academy of Pediatrics, as follows: Drs. Isaac A. Abt, Chicago; William N. Bradley, Philadelphia; Louis W. Sauer, Evanston, Ill., and John Ruhrah, Baltimore.—The seventh annual meeting of the Central Society for Clinical Research will be held in Chicago, November 2-3, at the Medinah Michigan Avenue Club.—The Central States Dermatological Society will hold its annual meeting in Buffalo, November 3.

Meeting of College of Surgeons.—The twenty-fourth clinical congress of the American College of Surgeons will be held in Boston, October 15-19, with headquarters at the Statler and Copley-Plaza hotels. Addresses to be delivered at evening meetings include the John B. Murphy Oration in Surgery by Dr. Donald C. Balfour, Rochester, Minn., on "Principles of Gastric Surgery," and a fracture oration on "The Unsolved Fracture," by Dr. Kellogg Speed, Chicago. Special features of the program will be a symposium on cancer, a fracture conference and one on industrial medicine and traumatic surgery, and a community health meeting.

Resolution Condemns Indiscriminate Use of Radium.—The American Radium Society at its annual meeting in Cleveland adopted resolutions criticizing commercial laboratories which give advice or directions for the use of radium. The same criticism was applied to institutions that rent or furnish radium to members of their staffs or persons outside the staffs who are unskilled in the application of radium and also to certain individual owners of radium. The society considers approval by the National Board of Radiological Examiners as the minimum standard for those assuming the responsibility of using radium. The resolutions recommended refusal of advertising matter in state and national journals when the firms concerned are advertising a consulting service or are advertising such service through the mails. They further disapproved any physician's association with a firm that carries on such advertising but approved an informal medical consultant for guidance of companies that refrain from advertising such professional service, either publicly or privately. The ethical commercial company is a necessity, the resolutions emphasized; it is the advertised consulting service that is deprecated. Restrictions on the advertising of a medical service will in no way hamper qualified radiologists in obtaining supplies, it was asserted. In another resolution the society stated its belief that it is justifiable to produce a second degree radiodermatitis when it is necessary in order to give sufficient treatment to overcome malignant disease. These resolutions were also approved by the board of chancellors of the American College of Radiology and the Section on Radiology of the American Medical Association.

FOREIGN

Cameron Prize Awarded.—Sir Edward P. Sharpey-Schafer, emeritus professor of physiology, University of Edinburgh, received the Cameron Prize in practical therapeutics awarded by the university in recognition of the advances in therapeutics arising out of his discoveries in endocrinology. Sir Edward, now 83 years old, retired in 1933. He has received many honorary degrees and medals from scientific societies and is widely known as the originator of the Schafer prone pressure method of artificial respiration. The award was made at the recent commencement at Edinburgh.

Congress on Industrial Medicine.—The Seventh International Congress on Industrial Accidents and Diseases will be held in Brussels in July 1935. The congress has been divided into three sections, each of which will deal with two subjects. The section on surgery will consider delayed effects of injuries to the cranium and traumatism of the hand and fingers; the section on occupational diseases, prevention of industrial dusts and pathologic action of gases escaping from veins of coal mines; and a joint session will take up objective manifestations of pain and electricity. For information address the secretary general of the congress, Dr. Leo Dejardin, 23 Rue de Commerce, Brussels; Dr. Fred H. Albee, 57 West Fifty-Seventh Street, New York, American president of the national committee for the section of accidents, or Dr. Emery Hayhurst, state department of health, Columbus, Ohio, American president of the national committee for the section of diseases.

Government Services

Discontinue Medical R. O. T. C. Units

With the graduation of the last remaining classes in June 1935, all medical department units of the reserve officers' training corps will be definitely discontinued, the war department has announced. According to the announcement, this will complicate the problem of procurement of medical department reserve officers, since these units have been the source of more than 50 per cent of the new appointments in this section of the officers' reserve corps. It is believed that the interest of medical and related personnel in the officers' reserve corps can be maintained by the establishment of proper contact with class A medical, dental and veterinary colleges. Effort should be made to interest young men who have just received their degrees, these applications to be solicited by specially designated contacting officers. Changes in army regulations have been approved which authorize the waiver of the requirement of license and actual engagement in practice of graduates of class A medical, dental and veterinary colleges in cases in which the applicants are commissioned at time of graduation. This permits the commissioning of medical graduates, as has been done in the case of medical students of the reserve officers' training corps in the past.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 8, 1934.

The Prevention of Road Accidents

If the dreadful toll of deaths and injuries on the roads shows no diminution, this is not due to any want of efforts on the part of the authorities. Indeed, it is possible that their efforts are producing effects that are counteracted, or more than counteracted, by the constant increase of automobile traffic. No figures have been published showing the relation of accidents to the amount of this traffic. The latest measure, which is a success, is the marking on the roadway of recognized crossing places for pedestrians, following the example of Paris. If a pedestrian is injured on one of these, the responsibility of the motorist is much increased. The minister of transport, Mr. Hore-Belisha, has set up a standing road safety council, over which he will preside. This body will meet at least once a week. It will be representative of all sections of road users. The first difficulty is to reconcile their conflicting claims. Among the organizations, the principal officers of which the minister has seen, are the Automobile Association, the Royal Automobile Club, the Commercial Road Users Association, the British Road Federation, the National Safety First Association, the Cyclists Touring Club, and the Pedestrians Association. As the result of the conversations all the officers of these bodies have undertaken to help in every possible way to reduce the number of accidents on the road and have readily acceded to the wish that they visualize the problem from a national rather than from a sectional angle. These organizations will combine in the formation of a standing council, which will discuss at regular meetings to be held at the ministry of transport all questions that have heretofore been considered solely from the points of view of the various organizations. To this council will be added representatives of local authorities, the police and the insurance companies. An important matter to which the minister is paying special attention is the obtaining of information regarding places where accidents occur most frequently. Observers will be sent to keep constant watch on "black spots" and to report defects that may be discovered in the control of traffic or obstacles that can be removed. The minister will adopt two methods: He believes that much good can be accomplished by the constant education of the public on the danger of the roads and the precautions necessary for all road users. His second method is regulations as to traffic. His decision to provide crossing places for pedestrians was prompted by the fact that the highest percentage of accidents occur to pedestrians. Since they were introduced into London, only one fatal accident has occurred at one of these crossings. On the other hand, most of the accidents to pedestrians in built-up areas occur where these crossings are some way off. A new order is the forbidding of the use of bicycles to carry more than one person unless it is specially constructed for the purpose.

Another New Cancer Treatment Exploded

Considerable and apparently undeserved space is given in the *Times* to the latest claim of a discovery with regard to cancer. At the Congress of International Science held at Frankfurt, Dr. Brehmer claimed that he had discovered a bacterium that causes cancer and was named by him *Siphonospora polymorpha*. Of Dr. Brehmer's claim it need only be said that it has excited incredulity even in his own country. A practical suggestion based on it has been confuted in England. As this bacterium develops best in a strongly alkaline medium, a treatment for cancer has been suggested, which includes bringing the patient's blood from the alkaline toward the acid side and regulating it

at a p_{H} between 6.8 and 7.1. In a letter to the *Times* Dr. Samson Wright, professor of physiology in the University of London, points out that this treatment is dangerous and not new. In animal experiments, disturbance of the blood reaction to this extent is always fatal, and in man a similar result is to be expected. Some ten years ago Mr. T. H. Kellock, surgeon to the Middlesex Hospital, which for a century has specialized in the investigation and treatment of cancer, tested the hypothesis that a moderate increase in the acidity of the blood might be of value in the treatment of cancer. But no improvement was observed in any of the patients so treated. Thus this apparently highly scientific work, which occupies nearly two columns of the *Times*, turns out, like a good deal of German investigations of the kind, to be only pseudoscientific.

The Storage of Food

At the annual meeting, at Aberdeen, of the British Association for the Advancement of Science, Sir Frank Smith, secretary of the department of scientific and industrial research, described recent advances that have been made in the storage of food. Most of the work is done at the research station of the department in Torry, Aberdeen, as much of it deals with the fishing industry. A smoking kiln heated by gas or electricity has been evolved to replace the smoldering fire of sawdust controlled simply by the curer himself and still used for converting herrings into kippers. This ancient method is at the mercy of the weather as to temperature and humidity. The Torry plant enables any desired cure to be produced with certainty. The salt cure of herrings has been combined with a process of chilling to produce a mild salted herring.

For the white fish trade—cod, halibut, plaice—investigations have shown how the unsatisfactory trawler storage of the catch in crushed ice can be improved. When landed the catch may be 17 days old, while the crushed ice can hold it fresh for only six or seven days. Research has found a solution by the freezing of the catch in cold brine at minus 20 C., at which temperature the growth of bacteria is completely arrested and the freezing enables the fish to be stored for three months. On thawing it is as good to look at and to eat as if it just came out of the sea.

For halibut a floating factory ship of 10,000 tons has been fitted up for the brine freezing of 4,000 tons of halibut at the rate of 70 tons a day. In May the ship goes to the Davis Straits, off the west coast of Greenland, where the fish are caught. In October it returns to Hull and there acts as a floating store. On the ship cod liver oil is manufactured and halibut livers are frozen and stored. Several other factory ships are at work on this principle.

MEAT FROM ABROAD

In Great Britain \$5,000,000 a day is spent on food brought from abroad, and the process that makes this possible is refrigeration. It has been found possible to stop completely the self-induced deterioration of meat by enzymes or organisms naturally present in the meat itself and to stop bacterial infection of the meat sufficiently to keep it good as a food. Mutton, lamb and pork are preserved by freezing, but freezing, as distinct from chilling, is unsatisfactory for beef, as the crystals of ice disrupt the muscle fibers and when the meat is thawed the water is not entirely reabsorbed but drains away and carries with it proteins, salts and pigments. The solution has been found to be carriage of the beef in an atmosphere containing from 10 to 20 per cent of carbon dioxide. Last year under these conditions a cargo of chilled beef was successfully brought for the first time from New Zealand. Rapid developments of this method are now being made by the shipping companies. Carbon dioxide storage also serves for apples and should help to overcome intolerance for cold, shown by the British apple.

Pensions and Politics

The necessity of establishing the budget of France on a solid basis compels the government to effect all possible retrenchments. One of the heaviest expenditures of the government at present is for war pensions. It is the general opinion that there have been abuses of the pension laws and that these are on the increase. One might assume that since 1914 death would have reduced the number of war victims, but the number actually increases, and the amount of money expended likewise is increasing, for the law permits a pensioner to demand a revision of his pension if he thinks that the state of his health is worse. In this way a shrewd man who succeeded in obtaining an annuity of 10 per cent of his normal salary, by reason of a stubborn cold or an attack of influenza suffered during the war, eventually is granted 50 per cent, or even 100 per cent, of his normal salary if he is able to find a court that will consider him tuberculous. That may result in an annuity of 17,600 francs (\$1,144), which may revert, in part, to his wife and to his children, in the event of his death, in addition to many further advantages that the law of 1919, as an expression of a feeling of compassion, accords to all persons who wore the uniform. What is especially objectionable is that, in allowing these increases of pension, no account is taken of the natural result of aging or of possible bad habits of the person applying for an increase. Many gouty, asthmatic and diabetic patients, and even patients with alcoholic cirrhosis, are drawing liberal pensions. Persons hastily considered tuberculous in 1918 and granted a large pension are today in good health, either because the original diagnosis was wrong or because they have succeeded in obtaining a cure. In some instances they have given up their occupation, while, in other cases, if their occupations bring a good yield, they add their pension to their regular income. Moreover, the right to demand a pension remains open indefinitely for any one who thinks that his present bad health had its origin in the war service, even though he never saw any actual fighting, having been merely employed in some office, far from the fighting lines. Irrespective of the time that has elapsed, the law gives him the right to present his claim. His application is examined by one of the special courts established in every department of France. Local political influence is brought to bear on this court, which is thus compelled to be generous. Nearly a billion dollars (almost a fourth of the annual budget) is devoted each year to pensions. It would be an easy matter to clip off two or three billion francs, which would be sufficient to balance the budget. But the pensioners are bound together in powerful political organizations, which exert an influence on the deputies, and when a few wise men demand a revision of war pensions wrongfully granted, they organize a vociferous opposition. Nevertheless, the government recently announced a reduction of 2 per cent in the pensions for disease only. Thereupon these pensioners immediately instituted an organized opposition and paraded the streets, uttering loud shouts in expression of their disapproval. The public contemplates these manifestations with a feeling of melancholy sadness, recalling the heavy taxes they have to pay by reason of these pensions, which they find themselves powerless to combat, in view of the demagogic system of politics that prevails. It is true that the same scandalous conditions are found in other countries, only the governments of Germany and Italy having been able to cope with any success with these deplorable abuses.

Restriction of the Number of Medical Students

Dr. Georges Portmann, professor of otorhinolaryngology at the Faculté de médecine de Bordeaux, elected senator last year,

has introduced a bill designed to limit the number of students to be admitted to the *facultés de médecine*. In 1930 the dean of the *Faculté de médecine de Paris* and the general secretary of the *Confédération des médecins de France* called attention to the deplorable situation in a circular letter addressed to the parents of pupils in the *lycées*, urging them to enlighten their children in regard to the future prospects of those who, under present conditions, take up the study of medicine. The number of physicians in France has increased from 16,815 in 1900 to 27,500 in 1928, whereas in this period the population has increased only two million. In spite of warnings, the situation has grown steadily worse. The number of students enrolled in the French medical schools has risen from 8,182 in 1929 to 9,780 in 1930, 9,842 in 1931, 10,242 in 1932 and 10,338 in 1933. The number of government diplomas issued to doctors of medicine by all the *facultés de médecine* was 1,076 in 1930, 1,102 in 1931 and 1,397 in 1932. But these figures correspond to the number of students enrolled five or six years previously. It is evident that in five years the number of graduates will be much greater. Overcrowding of the profession is reported from other countries. In Germany the Hitler government has recently decided that the number of medical students, which was 25,000 in 1933, shall be reduced to 15,000 in 1934. The bill proposed by Senator Portmann is not so rigid. It does not fix any maximum. It provides that the total number of medical students to be matriculated be fixed each year, according to the number of civil, army, naval and colonial physicians required, by a commission composed of the minister of public instruction, the minister of public health, the *Confédération des syndicats médicaux*, and the ministers of war, the navy department and the colonies. The selection would be made in two stages, the first at the end of the preparatory studies leading to the premedical diploma in physics, chemistry and biology, which affords entrance to the *facultés de médecine*, and the second after completion of the first year of study in the *facultés de médecine*. Only the number of holders of the premedical diplomas, as fixed by the ministerial commission, plus 50 per cent, would be admitted to the *facultés de médecine*, and this additional 50 per cent would be eliminated at the end of the first year of medical study. This regulation would concern only candidates for the government diploma, which grants the right to practice medicine in France (and in Rumania). As to the students enrolled for a university diploma, a degree much sought by foreigners, no limitation will be placed on their number; but the later transformation of a university diploma into a state diploma will be made more difficult and will be brought into harmony with the number of state diplomas fixed by the projected legislation.

Amebiasis in Paris

Amebiasis is rare in Paris, but possibly there are more cases than is generally supposed. Professor Lemierre has observed several hundred cases among the civil population in a period of fifteen years. The figures are much higher in the army and in the marine hospitals. The diagnosis is not so difficult as it appears at first. According to Lemierre, one cannot count on discovering pathogenic amebas other than in cases of typical intestinal amebiasis. The discovery of a hyperleukocytosis with neutrophil polynucleosis will be of great aid in distinguishing febrile hepatitis, without characteristic local symptoms, from malaria, typhoid or paratyphoid fever, tuberculosis and undulant fever. But the strongest proof of the amebic nature of the symptoms, when their character permits only a supposition, is the specific action of treatment with injections of emetine. The cases that figure in Lemierre's research show that, in the apparently hopeless cases, emetine works wonders, establishing thus, at the same time, the diagnosis. On the slightest suspicion therefore, he says, the physi-

cian should not hesitate to institute an emetine test treatment, which will be harmless if it has no curative effect. The only thing that one need fear is failure to recognize amebiasis when it presents itself.

International Conference on Chronic Rheumatism

An international conference was recently held at Aix-les-Bains, in Savoy, under the chairmanship of Prof. Fernand Bezançon, at which one topic, "Chronic Generalized Progressive Rheumatism," was discussed. In addition to the French members, a considerable number of foreign physicians were present, chiefly English. The conference was only a presentation of individual medical opinions (sometimes contradictory) on the pathogenesis of chronic generalized rheumatism, and no positive conclusions could be drawn from the conflicting papers. Prof. Fernand Bezançon and Dr. Weil endeavored to establish the limits of the pathologic condition termed "rheumatism" and admitted that the limits were rather uncertain in the neighborhood of degenerative osteo-arthritis. Contrary to the opinion of Charcot, the manifestations included under the name of generalized progressive rheumatism do not represent a homogeneous whole. Violence has been done to the facts in describing a symmetrical disease, regularly progressive, with a distal onset and a centripetal course. The deformations are commonplace. The trophic disorders for the most part develop late. There are, however, patients in whom one observes all these characteristics, and for these the authors proposed the term "progressive symmetrical polyarthritis" or, better still, "polyarthropathy"; for there is no direct proof that arthritis exists, in the strict sense of the word, or even that the disease is localized selectively in the joint. As for other cases, the symptoms develop differently. The authors discussed the mode of onset, the date of appearance, the progressive nature and the symptoms. Among these forms there are multiple varieties. From the radiologic point of view, four clinical types may be distinguished, according as there is an absence of radiologic lesions, destruction of articular contour, disappearance of bony segmentation or solely intense and diffuse decalcification. These aspects are not degrees in the morbid evolution; they represent exceptional states. Nevertheless, there is a family resemblance between all these cases. That is due not to the etiologic conditions nor to the state of the humors or the nature of the metabolism but to the conditions of the terrain. It is that which, by the progressiveness of the disease, creates the clinical type. Its cause lies in the mode of reaction of the subject, as a result of which, following the action of any factor—infectious, traumatic, proteinic or otherwise—disorders are produced in a joint, the essential character of which will be a tendency to become generalized.

Following the presentation of the previous paper, Loeper, D. Marchandau and J. Tonnet considered more particularly the metabolism of rheumatic patients, pointing out in them the excess of sulphur and calcium and the insufficiency of glutathione. Coste of Paris and Jacques Forestier of Aix-les-Bains surveyed the rôle of infectious elements in chronic generalized rheumatism (*gonococcus*, *streptococcus* and particularly *tubercle bacilli*). They scout the idea of a specific micro-organism.

Professor Gunzburg of Antwerp gave a critical survey of the modes of treatment to be applied to the various types of rheumatism. Professor Bach of London, in studying the anatomic aspects of generalized progressive rheumatism, which he called rheumatoid arthritis, attached great importance to the bone changes due to disturbed calcium metabolism. Mr. Scott of London recommended close study of roentgenograms to get an accurate conception of the disease and emphasized also the paramount rôle of decalcification. Professor Mouriquand of Lyons called attention also to the significance of the endocrine factors and the part played by the parathyroids. The

thyroid, the ovary and other organs. Professor Maranon of Madrid discussed at considerable length the diagnosis of various forms of progressive chronic rheumatism. Weissebach and Françon considered the prognosis. Professor Kahlmeter gave his interpretation of examinations of the blood of rheumatic patients. Professors Giraud and Puech of Montpellier presented a comprehensive paper on the thermic treatment of rheumatism.

The Cause of Pain in Angina Pectoris

By means of a type of calorimeter the physiologist Rein of Göttingen has succeeded in measuring directly the amount of the coronary blood flow, which it was found varies somewhat from hour to hour, being dependent on the performance of the heart. In contrast with the other vessels that are subordinate to the sympathicus, the coronary vascular system is dependent on the vagus tonus.

In the opinion of Professor von Bergmann, who spoke recently on angina pectoris before the Berlin Medical Society, the pain may be fully explained by the deficiency of oxygen in the heart muscle and the resulting injuries, the partial suffocation resulting in an impaired function ranging from mild oxygen impoverishment, acid formation and slight attacks of angina pectoris to cardiac infarct. Pain conduction is by way of centripetal nerves in the heart. An illuminating demonstration of the importance of the vagus in connection with the coronary blood flow consists in the expansion of the lowest portion of the esophagus by means of a rubber balloon, applied to the dog, which evidently irritates the vagus nerves and precipitates an attack, the same as pressure on the sinus caroticus; the expansion causes a reflex change in the blood flow. The connection between attacks of angina pectoris and the ingestion of full meals, increases of blood pressure and attacks of emotion is widely known. The electrocardiogram possesses great value as a diagnostic aid for determining the gravity of coronary changes in the heart, and particularly for the diagnosis of the cardiac infarct. The typical changes are the inverted secondary deflection (negative T), the high first deflection, the splitting of the R wave, the iso-electric secondary deflection, and the like. Rabbits poisoned by carbon monoxide and hence deficient in hemoglobin present similar aspects in the electrocardiogram. The von Bergmann "school" found in anemized rabbits anatomic changes in the form of typical necroses of the heart muscle. This observation appears to afford an important basis for the understanding of angina pectoris in man. One can produce also in human subjects the electrocardiogram corresponding to that of angina pectoris; for example, in connection with examinations in the subpressure chamber, such as are instituted in testing persons with reference to their aptitude as aviators. In such tests an artificial process is employed to render the blood deficient in oxygen, and one finds in examinations based on an assumed elevation of from 6,200 to 8,000 meters just such types of electrocardiogram. A further proof lies in the fact that in persons with a tendency to angina pectoris, at an early date, before the appearance of the subjective suffocation phenomena, the typical changes in the electrocardiogram are observable if one allows such persons to breathe between attacks while subjected to a deficiency of oxygen. These changes soon disappear as soon as an adequate supply of oxygen becomes available.

Oxygen deficiency of the heart muscle is shown beyond doubt to be the cause of pain associated with angina pectoris. The causes that lead to a narrowing of the coronary artery and thus to oxygen deficiency are various; for example, a severe

hemorrhage from a gastric ulcer may precipitate an attack. The most frequent cause is coronary sclerosis. The terms "angina pectoris falsa," "vera," "minor" and "major" are now no longer needed. Effort angina and angina pectoris ambulatoria, in the light of present-day knowledge of oxygen deficiency of the heart muscle as the precipitating cause of the attack, are readily understood. It is evident, therefore, that coming to a complete standstill on the street is the most suitable therapy in the event of an attack of angina pectoris, since such action gives the heart an opportunity to adapt itself to the oxygen deficiency.

The Heritability of Diseases of the Intestinal Tract

Dr. H. Kalk discussed before the Berlin Medical Society the heritability of diseases of the intestinal tract. In from one fourth to one third of the families of ulcer patients there is a history of diseases of the stomach. There are, moreover, extensive family trees of so-called ulcer families. An ulcerous disease presents itself earlier and in a more severe form when the hereditary trend is strong. Likewise during the course of the disorder (site of the ulcer, hemorrhages, perforation) marked familial aspects are often observable, especially in enzygotic twins. Frequency of sensitive stomach and cancer of the stomach in ulcer families points to a hereditary organic inferiority of the stomach. In carcinoma of the intestinal tract, cases of marked similarity as regards age and site in several members of a family have been observed. In gastritis, the frequent occurrence of sensitive stomach or a tendency to indigestion in certain families makes a hereditary predisposition very probable. Achylia is of frequent occurrence in families with a prevalence of pernicious anemia. A tendency to diarrhea appears to be the result of an inherited easily disturbed vegetative nervous system.

On the side of liver disorders there is a familial prevalence of an increase of the bilirubin content of the blood (constitutional hyperbilirubinemia); the dominant hereditary hemolytic icterus has, however, no connection. Also a familial tendency to icterus is observed. In gallbladder disorders—that is, in the pathogenically closely associated stone disorders, inflammation and disturbance of function of the gallbladder—the symptoms, much as in ulcer disorders, appear relatively early if the hereditary predisposition is marked (usually on the female side).

Criminality in Twins

A previous letter (THE JOURNAL, March 31, p. 1098) dealt with research on the subject of criminality in twins. At a meeting of the Deutsche Gesellschaft für Vererbungswissenschaft, Dr. Heinrich Kranz, of the Kaiser Wilhelm Institut für Anthropologie, menschliche Erblehre und Eugenik, announced the results of further research in this field. The examinees were inmates of the Prussian prisons. Up to the present time, twenty-seven enzygotic and thirty-seven dizygotic twins have been studied. In seventeen of the enzygotic groups, both twins had received a sentence for a crime or misdemeanor; in ten of the groups only one of the twins had incurred a penalty. Agreement, or concordance, was evidenced in 63 per cent, and differentiation, or discordance, in 37 per cent. In eighteen dizygotic groups, both twins had received a sentence; in nineteen groups, only one twin (46 per cent and 54 per cent, respectively). The agreement, or concordance, does not run as high as in the researches of J. Lange and of Legras. In the penalized groups of twins the enzygotic groups reveal great similarity in the number of penalties incurred and as to the time when the first penalty was imposed, but less similarity in the severity of the penalties and in the nature of the crimes and misdemeanors. The dizygotic groups show, on the other hand, marked differences in all these points. In the groups composed of a male and a female, the differences between the

enzygotic and the dizygotic groups were less marked. The hereditary influence is therefore strongest with reference to the repetition of the crimes, and next with regard to the time of onset of the criminal conduct. The severity of the penalties and the type of crime committed depend more on environmental influences. Combining the results secured by J. Lange, Legras and Kranz in their examination of twin groups with respect to criminality, one finds thirty enzygotic twin groups concordant and thirteen discordant (70 and 30 per cent, respectively); twenty dizygotic twin groups concordant and thirty-nine discordant (34 and 66 per cent, respectively). A deeper perception of the differences and the similarities in the two groups will be secured when a detailed examination of the individuals has been made.

ITALY

Prophylaxis of Ancylostomiasis

During the construction of the railway line from Florence to Bologna, which extended over several years, the prophylactic crusade against ancylostomiasis assumed great importance. The results of this crusade were recently announced in a report of the ministerial sanitary commission, of which Professor Alessandrini, director of the institute of parasitology of the University of Rome, was chairman.

It was necessary to overcome many difficulties in order to prevent the development of larvae in the environs of the workmen. Laboratories were established, and all the workmen were given preventive examinations at regular intervals, particularly those who were engaged in underground work. Likewise, first aid stations were created, with facilities for isolation of patients. The work-yards and the bunkhouses were provided with good drinking water, baths with hot and cold water, and stoves; and periodic disinfection of the premises was instituted.

Owing to the adoption of these measures, not a single case of ancylostomiasis was diagnosed during the construction of the railway, although ova of the helminth were often found in workmen who applied for work. Such applicants were either not employed or were given thorough treatment before they were hired.

Research on Rheumatism

At the International Congress on Rheumatism, in Moscow, Professor Chini of Rome presented a paper prepared in collaboration with Professor Lusena, on the pathology of rheumatism. He endeavored to show that no absolutely reliable evidence has been adduced to prove a streptococcic etiology of rheumatism or a focal and allergic pathogenesis. Nevertheless, in many cases of rheumatism corresponding to the streptococcic rheumatism of Graff, it would seem that the streptococcus played an important part, and these pseudo types of rheumatism find also a counterpart in experimental researches in which the presence of a chronic streptococcic focus, developed heretofore in the rabbit with arthrophile micro-organisms, gives rise to a systemic granulomatosis similar to the rheumatic manifestation in man.

The Academy of Medical Sciences

The Academy of Medical Sciences met recently in Palermo, under the chairmanship of Professor Giuffrè. Mottarella reported the results of his studies on the action of the hematopoietic hormone of the liver, prepared according to the Piazza technic in thirty-three cases of primary and secondary, and plastic and aplastic, anemia. The hormone was administered by the parenteral route in daily doses of 0.04 Gm. In almost

all cases, before the appearance of the blood changes, the patients experience a sense of euphoria. Later on, an increase in the number of erythrocytes, or often even a hyperglobulia, becomes manifest. In the primary forms there is observed a gradual disappearance from the circulation of the mature types and a readjustment of the corpuscular values. In these cases, however, when the administration of the hematopoietic hormone is discontinued, the anemia gradually reappears, whereas in secondary anemias, when the normal erythrocyte count is reached, it persists. Often also secondary effects are produced, such as a decrease in the size of the spleen and a clearing up of the skin. In some cases malaria parasites appear in the blood stream, owing to reactivation of a latent process. In some types of aplastic anemia, even prolonged administration of the hematopoietic hormone causes no improvement in the patient's condition. To these forms belong the anemias associated with cancer and those due to *Ancylostoma duodenale*, in which, however, the nonsusceptibility to hormones is transitory and disappears when the parasite is eliminated.

Piazza, on the basis of studies on the hematopoietic hormone isolated by him, pointed out the existence in the liver of a normal internal secretion that regulates the blood mass by means of a hormone that reacts on the hematopoietic organs. In the pathogenesis of the anemias this internal secretion must be kept in mind and the anemias themselves must be interpreted as hematopoietic insufficiencies due either to insufficient secretion by the liver of the blood-regulative hormone or to insufficient sensitivity to the hormone on the part of the hematopoietic organs. In the latter case, a more than normal stimulus is needed to produce hematopoiesis, a stimulus that the liver is unable to furnish.

Standardization of Methods of Anthropology

The international committee for the standardization of methods in anthropology and eugenics met recently in Bologna, under the chairmanship of Professor Frassetto, director of the Anthropologic Institute of the university. Professor Weninger, director of the Anthropologic Institute of the University of Vienna, spoke on the standardization of the methods of describing external somatic characters, and of the morphologic, anatomic and histologic complexes.

Professor Davenport, director of the eugenics section of the Carnegie Institution in Washington, proposed in his paper some new methods pertaining to anthropometry as applied to living subjects.

Professor Fischer, rector of the University of Berlin, suggested a questionnaire for the study of racial crossings, based on the analytic geneological method. The committee fixed the program of the activity of this new scientific body (S. A. S.). The society will publish a bulletin that will summarize all the publications dealing with anthropologic methodology. Contributions on the researches of societies and of individual investigators of all countries will be solicited. The material thus collected will be evaluated and coordinated and will serve as the basis for the compilation of the *Codex Anthropologicus*, which will be published by the S. A. S.

Dr. Galegari

The death of Dr. Giovanni Battista Galegari, member of the army medical corps, with the rank of lieutenant general, at the age of 74, is announced. He was for many years department head in the Ospedale di Milano. During the war he was director of the army medical corps and distinguished himself by the organization of the crusade against cholera and exanthematic typhus. He was the director, in succession, of the sanitary service of two armies. After the war he served for years as general director of the army medical corps, in the ministry of war.

Marriages

ROY ELVIN NICODEMUS, Danville, Pa., to Miss Geraldine Frances Sullivan of Elmira, N. Y., in New York, August 3.

ALBERT WARREN KITTS, Kennett Square, Pa., to Miss Ann Stambaugh of Philadelphia, in Middlesboro, Ky., recently.

GILBERT MORTIMER HALPERN, Honolulu, Hawaii, to Miss Dorothy C. Waters of Philadelphia, July 5.

JOHN LEONARD PROBASCO, Bloomington, Ill., to Miss Laurastine Welch of Lexington, August 18.

LOVICK WILSON PIERCE, Brunswick, Ga., to Miss Julia Carmichael Bell of Augusta, August 6.

JOHN ROBERT HARDING, Cincinnati, to Miss Esther Beatriz Garcia of Tampa, Fla., September 1.

ERWIN H. GRUMKE, Lime Ridge, Wis., to Miss Alma M. Schroeder of Madison, September 1.

CLIFFORD HOGAN STRIPLING to Miss Louise Bennett, both of Jacksonville, Texas, July 27.

LLOYD M. SOUTHWICK to Miss Ruth Tarpley, both of Edinburg, Texas, September 1.

CARL A. S. GUNDERSON to Miss Modesta Elmer, both of Madison, Wis., August 28.

MICHAEL GLEASON, Mendota, Ill., to Miss Celeste Brahaney of Buffalo, September 4.

HENRY H. SLATER to Mrs. Emma A. Johnson, both of Deer Park, Wash., July 7.

EDWARD MARKEY PULLEN to Miss Joan Travers, both of New York, June 30.

LESLIE LORAN HUNTLEY, Omaha, to Miss Mary Bergdall in Chicago, July 7.

ROBERT F. PURTELL to Miss Florence McCormack, both of Milwaukee, June 6.

ARNOLD W. HACKFIELD to Miss Margaret I. Donley, both of Seattle, July 10.

HENRY W. KASSEL to Miss Marie Lasley, both of Kansas City, Kan., June 9.

JOHN STEPHEN WITKOWSKI, Niagara Falls, N. Y., to Miss Kubala, May 30.

AMBLER CASKIE PRUNER to Mrs. Ross Shotwell, both of Omaha, recently.

JOEL W. BAKER to Miss Mary Elizabeth Russell, both of Seattle, July 26.

Deaths

Malcolm A. Bliss, St. Louis; Chicago Medical College, 1891; an Affiliate Fellow of the American Medical Association; member of the American Neurological Association and the American Psychiatric Association; formerly a dentist; at one time instructor in clinical psychiatry, Washington University School of Medicine; formerly member of the board of managers of the State Eleemosynary Institutions of Missouri; served during the World War; for many years on the staffs of the City Hospital, City Sanitarium, St. Luke's, Jewish and DePaul hospitals; aged 71; was found dead, September 4, of coronary sclerosis.

Charles Victor Roman, Nashville, Tenn.; Meharry Medical College, Nashville, 1890; emeritus professor of ophthalmology, otology and laryngology and professor of medical history and ethics at his alma mater; past president of the National Medical Association; co-founder of the John A. Andrew Clinical Society, Tuskegee Institute, Tuskegee, Ala.; at one time director of the department of health, Fisk University; member of the board of directors of the George W. Hubbard Hospital; aged 70; died, August 25, of cerebral hemorrhage.

Frederick W. Sears, Syracuse, N. Y.; Syracuse University College of Medicine, 1886; member of the Medical Society of the State of New York; professor emeritus of hygiene and sanitation at his alma mater; past president of the Onondaga County Medical Society; district state health officer; formerly health officer of Syracuse; for many years on the staff of the Syracuse Memorial Hospital; aged 75; died suddenly, August 31, in the Murray Hospital, Butte, Mont., of cerebral hemorrhage.

James Joseph Mooney, Buffalo; Niagara University Medical Department, Buffalo, 1890; member of the Medical Society of the State of New York and the American Laryngological, Rhinological and Otological Society; fellow of the

American College of Surgeons; on the staffs of the Buffalo Hospital of the Sisters of Charity, St. Mary's Infant Asylum and the Buffalo City Hospital; aged 69; died, September 4, of myocarditis and cardiac decompensation.

Thomas Weston Chester, Hartford, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Connecticut State Medical Society and the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; on the staff of the Hartford Hospital; aged 68; died, August 22, in Columbia, of coronary thrombosis.

James Harvey Seymour of Los Angeles; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; formerly professor of surgery and clinical surgery, University of Southern California Medical Department; fellow of the American College of Surgeons; visiting surgeon to the Los Angeles General Hospital; aged 64; died, August 13, in the California Hospital following an operation for intestinal obstruction.

George Christian Schaeffer, Columbus, Ohio; Miami Medical College, Cincinnati, 1896; formerly assistant professor of ophthalmology, Ohio State University College of Medicine; fellow of the American College of Surgeons; served during the World War; on the staffs of the Children's, Grant, Mount Carmel and White Cross hospitals; aged 64; died, August 12, in Laporte, Ind., of carcinoma.

Ralph Witt Staley of Cincinnati; Medical College of Ohio, Cincinnati, 1901; member of the American Urological Association; assistant professor of urology, University of Cincinnati College of Medicine; served during the World War; on the staffs of the Cincinnati General and St. Mary's hospitals; aged 55; died, August 29, of heart disease.

Joseph Henry Branham, Rehoboth Beach, Del.; College of Physicians and Surgeons, Baltimore, 1879; at one time professor of clinical surgery, University of Maryland School of Medicine, Baltimore; formerly on the staff of the Franklin Square Hospital, Baltimore; aged 77; died, August 19, in the Beebe Hospital, Lewes, of bronchopneumonia.

James Brown Kinnaird, Lancaster, Ky.; Bellevue Hospital Medical College, New York, 1882; member, for many years treasurer and at one time vice president of the Kentucky State Medical Association; formerly secretary of the Garrard County Medical Society; for many years member of the city council; aged 77; died, July 24, of arteriosclerosis.

Alto Freed Mahoney, Monroe, N. C.; University of Louisville (Ky.) School of Medicine, 1911; member of the Medical Society of the State of North Carolina; served during the World War; medical director and superintendent of the Ellen Fitzgerald Hospital; aged 47; died, August 29, in a hospital at Charlotte, of pernicious anemia.

John B. Bond, Martin, Tenn. (licensed in Tennessee in 1907); for many years director of the bureau of vital statistics, state department of health; formerly health officer of Obion County; at one time superintendent of the Western State Hospital, Bolivar; aged 60; died, September 2, in Nashville, of heart disease.

Irving Ferguson Barnes, Oyster Bay, N. Y.; University of the City of New York Medical Department, 1890; member of the Medical Society of the State of New York; for many years medical inspector of the local schools; aged 67; died, September 6, in a hospital at Winsted, Conn., of cerebral hemorrhage.

Charles Lane Hinchey of Rochester, N. Y.; Johns Hopkins University School of Medicine, Baltimore, 1907; served during the World War; aged 58; on the staffs of the Strong Memorial Hospital, Monroe County Hospital and the Rochester General Hospital, where he died, August 26, of heart disease.

George Roeder, Omaha, Neb.; Omaha Medical College, 1892; member of the Nebraska State Medical Association; veteran of the Spanish-American War; formerly on the staff of St. Francis Hospital, Grand Island; aged 72; died, August 29, of pneumonia, following a fractured arm sustained in a fall.

Montgomery Thomas McCulloch, Elkton, Va.; Medical College of Virginia, Richmond, 1907; member of the Medical Society of Virginia, and formerly councillor of the Tenth District; past president of the Botetourt County Medical Society; aged 54; drowned, July 14, while fishing.

John Hancock Fuchs of New Rochelle, N. Y.; Bellevue Hospital Medical College, New York, 1889; veteran of the Spanish-American War; aged 65; on the staff of the New Rochelle Hospital, where he died, September 5, of carcinoma of the cecum and intestinal obstruction.

Clarence Earl Smart, Granville, Ill.; Chicago College of Medicine and Surgery, 1917; member of the Illinois State Medical Society; served during the World War; on the staff of St. Margaret's Hospital, Spring Valley; aged 45; died suddenly, August 30, of cerebral hemorrhage.

Harry John Thompson, Indianapolis; Harvard University Medical School, Boston, 1894; served during the World War; on the staff of the Veterans' Administration Facility; aged 65; died, August 12, at his summer home in Culver, of injuries received in an automobile accident.

Jesse Nathaniel Roe, Riverside, Calif.; University of Buffalo School of Medicine, 1908; member of the California Medical Association; formerly on the staffs of the Memorial, Lafayette, General and City hospitals, Buffalo; aged 62; died, August 4, of coronary thrombosis.

Oscar La Borde, Columbia, S. C.; Medical College of the State of South Carolina, Charleston, 1905; member of the South Carolina Medical Association; on the staffs of the Columbia and South Carolina Baptist hospitals; aged 55; died, July 31, of chronic myocarditis.

Edward J. Libbert, Aurora, Ind.; Cincinnati College of Medicine and Surgery, 1889; for more than six years mayor of Aurora; secretary and past president of the Dearborn-Ohio County Medical Society; aged 65; died, August 2, of heart disease.

Clarence Hugh Harwood, Charleston, Ill.; University of Louisville (Ky.) School of Medicine, 1910; formerly mayor; medical director and part owner of the Oakwood Hospital; aged 51; was killed, September 1, in an automobile accident.

Warren F. Eckles, York, Neb.; College of Physicians and Surgeons, Keokuk, Iowa, 1898; member of the Nebraska State Medical Association; on the staff of the Lutheran Hospital; aged 60; died suddenly, August 16, of angina pectoris.

John Willis Macy, Boston; State University of Iowa College of Medicine, Iowa City, 1928; member of the Minnesota State Medical Association; associated with the Lahey Clinic; aged 32; died, August 10, of ulcerative colitis.

Hansford Hall Milbee, Marshfield, Wis.; Trinity Medical College, Toronto, Ont., Canada, 1896; president of the Marshfield Clinic; aged 63; surgeon in chief at St. Joseph's Hospital, where he died, August 21, of heart disease.

Frank Joseph Patera, Chicago; Rush Medical College, Chicago, 1883; on the staff of St. Mary of Nazareth Hospital; aged 73; died, September 12, at Rhinelander, Wis., of hypertrophy of the prostate gland and chronic nephritis.

J. Ralph La Rue Redfield, Bangkok, Siam; Jefferson Medical College of Philadelphia, 1919; for many years connected with the public health department of the Siamese government; aged 49; died, July 17, of pneumonia.

Loftus Harley Francis, Cotati, Calif.; California Eclectic Medical College, Los Angeles, 1897; member of the California Medical Association; aged 75; died, July 27, of uremia, diabetes mellitus and adenocarcinoma of the prostate.

Jose Lisandro Medina, New York; University of the City of New York Medical Department, 1891; Nicaraguan vice consul; aged 70; on the staff of the French Hospital, where he died, August 25, of bronchopneumonia.

John W. Rodwell, Mocksville, N. C.; College of Physicians and Surgeons, Baltimore, 1895; member of the Medical Society of the State of North Carolina; aged 68; died, August 12, in a hospital at Charlotte, of nephritis.

Matthew Blair St. John, Bristol, Tenn.; Hospital College of Medicine, Louisville, Ky., 1903; aged 55; died, August 19, in the George Ben Johnston Memorial Hospital, Abingdon, Va., of acute dilatation of the heart.

Byron Francis Dawson, Los Angeles; University of Michigan Medical School, Ann Arbor, 1886; Jefferson Medical College of Philadelphia, 1897; aged 76; died, August 21, of arteriosclerosis and nephritis.

Joseph William Forshey, Lowell, Ohio; Starling Medical College, Columbus, 1903; member of the Ohio State Medical Association; aged 64; died, August 16, of heart disease, arteriosclerosis and hypertension.

Earl Wayne Gayer, Rochester, N. H.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; aged 52; died, August 16, of uremia, diabetes mellitus and chronic nephritis.

Rowland Rodman Robinson, Wakefield, R. I.; Harvard University Medical School, Boston, 1888; veteran of the Spanish-American War; aged 72; died, August 26, of carcinoma of the liver.

Abraham Le Witt, Hartford, Conn.; Cornell University Medical College, New York, 1900; member of the Connecticut State Medical Society; aged 62; died, August 11, of arteriosclerotic heart disease.

Samuel S. Gross, Denton, Kan.; Kentucky School of Medicine, Louisville, 1894; Ensworth Medical College, St. Joseph, Mo., 1909; aged 59; died, July 21, in Lawson, Mo., of a self-inflicted bullet wound.

Frederick Kenan, Upper Sandusky, Ohio; Starling Medical College, Columbus, 1906; past president of the Wyandot County Medical Society; aged 59; died, August 15, of coronary embolus.

Levi Samuel Long, St. Joseph, Mo.; Baltimore Medical College, 1892; formerly on the courtesy staff of the Missouri Methodist Hospital; aged 62; died, August 10, of cerebral hemorrhage.

Martin A. Kleinhans, Milwaukee; Milwaukee Medical College, 1902; aged 60; died, August 4, in St. Mary's Hospital, of chronic myocarditis, carcinoma of the sigmoid and intestinal obstruction.

John Joseph De Vereaux, Warrenton, Mo.; Barnes Medical College, St. Louis, 1907; also a pharmacist; served during the World War; aged 53; died, August 18, of coronary occlusion.

Paul Greene Rowand, New Canaan, Conn.; University of Vermont College of Medicine, Burlington, 1934; aged 24; died, July 3, in Montreal, Que., Canada, of aneurysm of the circle of Willis.

Oscar Charles Reeve, Oakland, Calif.; University of California Medical Department, San Francisco, 1905; aged 58; died, July 19, of Buerger's disease, arteriosclerosis and coronary disease.

Constantine S. Kryszinski, Chicago; Hering Medical College, Chicago, 1909; for many years on the staff of St. Elizabeth's Hospital; aged 47; died, August 1, of carcinoma of the lung.

Robert Lee Hammond, Frederick, Md.; University of Maryland School of Medicine, Baltimore, 1882; aged 72; died, August 20, of chronic nephritis, arteriosclerosis and myocarditis.

Thomas P. Birdsall, Newburgh, N. Y.; New York Homeopathic Medical College, 1878; aged 78; died, August 2, of cerebral arteriosclerosis, chronic nephritis and myocarditis.

Alfred Preston Bowen, Lynn, Mass.; Harvard University Medical School, Boston, 1904; formerly on the staff of the Lynn Hospital; aged 57; died, August 22, of heart disease.

Frank Eyre, North Henderson, Ill.; University of Pennsylvania School of Medicine, Philadelphia, 1876; aged 80; died, August 18, of heat exhaustion and myocarditis.

Richard Alexander Feild, Enid, Okla.; Bellevue Hospital Medical College, New York, 1880; aged 80; died, August 14, of pulmonary edema following cerebral hemorrhage.

Linneus Alton Roberts, Boston; Dartmouth Medical School, Hanover, N. H., 1893; aged 66; died, August 23, in the Charlesgate Hospital, Cambridge, of embolism.

Harvey Toor Olsan, Los Angeles; University of California Medical School, San Francisco, 1930; aged 29; died, July 5, of teratoma of the testicle with metastasis.

Oral De Witt Cunningham, Rockford, Ill.; State University of Iowa College of Medicine, Iowa City, 1924; aged 36; died, September 10, of agranulocytic angina.

J. Frank Heath, La Harpe, Kan.; University Medical College of Kansas City, Mo., 1905; aged 65; died suddenly, September 1, at Lane, of coronary thrombosis.

Marion Balfour Rockwell, Amherst, Mass.; University of Edinburgh Faculty of Medicine, Edinburgh, Scotland, 1899; aged 61; died, August 15, of carcinoma.

Jonathan Alfred Kackley, Pleasant City, Ohio; Columbus Medical College, 1882; aged 77; died, August 23, in the Wells Hospital, Cambridge, of heart disease.

L. William Ray, St. Louis; University Medical College of Kansas City, 1901; aged 64; died, July 23, in the Firmin Desloge Hospital, of heat prostration.

George Edward Routh, St. Paul; Miami Medical College, Cincinnati, 1878; aged 87; died, July 23, of myocarditis, bronchopneumonia and arteriosclerosis.

William Isaac McCowan, Navarre, Ohio; Medico-Chirurgical College of Philadelphia, 1909; aged 53; died, July 22, of carcinoma.

Louise Ross, Washington, D. C.; Boston University School of Medicine, 1907; aged 61; died, August 9, of pyelitis.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE: The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Dr. Gardner's Kidneyaid.—G. S. Cheney Co., Inc., Boston. Composition: Essentially pipsissewa leaves, althea root, sassafras bark and triticum. For Bright's disease, kidney, liver, bladder and blood disorders. Fraudulent therapeutic claims.—[N. J. 20936; June 1934.]

Ferrac.—Greenville Products Co., Greenville, Ala. Composition: Essentially sulphates of iron, aluminum, lime, magnesium, sodium and potassium, with water. "Tonic." Fraudulent therapeutic claims.—[N. J. 20937; June 1934.]

Exto-Rac.—Greenville Products Co., Greenville, Ala. Composition: Essentially sulphates of iron, aluminum, lime, magnesium, sodium and potassium, with water. For eczema, sores, douching purposes, etc. Not antiseptic. Fraudulent therapeutic claims.—[N. J. 20937; June 1934.]

Radium Cone No. 3.—Radium Cone Co., Long Beach, Cal. Composition: A brick containing radium, yielding 32.6 millimicrocuries of radon when left in one gallon of water eighteen hours. For indigestion, systemic poisons, rheumatism, etc. Fraudulent therapeutic claims.—[N. J. 20944; June 1934.]

P. C. Ointment.—Pacific Coast Proctological Clinic, Los Angeles. Composition: Essentially zinc oxide and volatile oils, including menthol, camphor and tar oils, in a petrolatum base. For hemorrhoids, rectal ulcers, boils, carbuncles, etc. Fraudulent therapeutic claims.—[N. J. 20945; June 1934.]

Nofal.—Lifol Co., Tulsa, Okla. Composition: Essentially coal tar creosote, rosin soap, alcohol and water. For eczema, falling hair, pyorrhea, etc. Fraudulent therapeutic claims.—[N. J. 20948; June 1934.]

THE CLAYTON E. WHEELER FRAUD

Another Piece of Mail-Order Quackery
Debarred from the Mails

Clayton E. Wheeler, M.D., of San Francisco and Los Angeles has for some years been carrying on a piece of mail-order quackery of the "gland-rejuvenation" type. In October, 1928, the California State Board of Medical Examiners revoked Wheeler's license to practice. In November, 1928, Judge Griffin vacated and set aside the Board's order. In May of this year, after an extensive hearing, the Post Office Department declared Wheeler's mail-order scheme a fraud and debarred it from the United States mails.

The first record in the files of the Bureau of Investigation of the Wheeler quackery was a full-page advertisement appearing in the Sunday magazine section of the Los Angeles Times. The advertisement purported to be a write-up by one Joseph D'Gee. According to this person—if there is such a person—Wheeler's treatments in chronic cases "gave favorable reaction immediately in some cases, bordering on the miraculous." According to the same report:

"Human efficiency is prolonged by improving physical strength and by the restoration of mental activity.

"The acuity of senses is regained and improved.

"Hardening of the arteries and high blood pressure are alleviated.

"Premature old age or actual senility is deferred.

"Mental depression is removed.

"Life's clock is turned back a number of years."

During the past ten years Wheeler has advertised extensively, his advertisements appearing not only in the Los Angeles Times, but in the San Francisco Examiner, Chronicle, Bulletin, Call and Post, and others. In addition to full-page newspaper advertisements, which must have cost Wheeler tens of thousands of dollars, he has put out booklets puffing himself and his alleged treatments. It should be mentioned at this point that in addition to his mail-order quackery, Wheeler apparently has conducted so-called clinics. In the case of the clinics, if his advertise-

ments are to be believed, his "treatment" consisted of the "injection in the walls of the abdomen of the gland needed."

As the injection treatment was obviously unsuited to the mail-order scheme, Wheeler sent to his dupes through the United States mails suppositories which were purported to contain certain glandular substances. The suppositories, which were to be used per rectum, according to Wheeler's own claim at the federal hearing, contained the following desiccated material:

Thyroid gland tissue.....	¾ grain
Whole pituitary tissue.....	1½ grains
Testicular substance.....	5 grains
Liver substance.....	5 grains
Prostatic substance.....	2 grains
Suprarenal Substance.....	1 grain

The quantities given were said to represent the amount in each suppository and totaled, it will be noted, 14¾ grains. The government analyst, however, who testified at the hearing declared that actually there was only 1½ grains of protein matter in the suppositories that Wheeler sent out, and in at least one of the samples examined, the animal tissue was found to be largely composed of striated muscle fibers and not glandular tissue at all!

In addition to twenty-six suppositories that constituted the "treatment," Wheeler also sent to his victims four tubes containing semi-liquid matter. The tube had a small rectal tip and the instructions were to use one tube a week, injecting the material into the rectum. According to the government analyst, the tubes contained some protein matter, with a small amount of phenol (carbolic acid) as a preservative. The suppositories, it should be added, contained, in addition to their animal tissue, some strychnine and brucin.

In Wheeler's booklets he published a picture of San Quentin prison and under it carried the statement: "Where Dr. Wheeler conducted research and gland experimental work with excellent results." It was brought out at the hearing that Wheeler never had any official connection with San Quentin prison and never conducted any research or experimental work in that institution. In fact, Wheeler admitted at the hearing that he had never performed any such operations at San Quentin.

Elsewhere in the same booklets Wheeler devoted a whole page to pictures of laboratory equipment which was described in the legend under the pictures as "Dr. Wheeler's Experimental Laboratory for Goat Serums." The facts of the matter were, according to information furnished by Dr. Pinkham of the California State Board of Medical Examiners, the pictures were actually those of a cocoa-butter suppository manufacturing plant of the A. E. Schmidt Company of San Francisco. The equipment had no more to do with "goat serums" than it had to do with making diphtheria anti-toxin.

Still elsewhere in the same booklets were pictures of Catalina Island and of some of the wild goats that are found there. Wheeler gave the impression that from 40,000 to 50,000 wild goats on Catalina Island had been made available to him for his gland work. On another page of the same booklet were pictures of Guadeloupe Island, showing huge numbers of "goats awaiting transportation." According to Wheeler, he had entered into a contract with "the owners of practically all the herds of wild goats on Guadeloupe Island" for his exclusive use. On still another page Wheeler reproduces a photograph of his private yacht—Yes, quackery pays!—in which he claimed to make "frequent trips to Guadeloupe Island." In this connection the following quotation from the memorandum of the Solicitor of the Post Office Department to the Postmaster-General in the Wheeler case is of interest:

"With respect to the statements in respondent's advertising literature relative to huge herds of wild goats on Catalina Island being made available to him, it appears that the testicular substance which Dr. Wheeler claims to use, does not come from such herds. The statement in the literature with respect to obtaining goats from the Island of Guadeloupe is also false, as Dr. Wheeler admitted to the post office inspector that he was not obtaining goats from that island."

The advertising, of course, carried the usual collection of testimonials. From these the public was led to believe that Wheeler's treatment would not only restore youth, but would cure pernicious anemia, arthritis, asthma, bronchitis, rheuma-

tism, lumbago, bronchial trouble, diabetes, paralysis agitans, sciatica, high blood pressure, heart trouble and other disorders and diseases.

It is worth noting in this connection that Wheeler claimed—via the testimonials—to cure angina pectoris. The government report shows that Wheeler did not believe sufficiently in his own magic to use it upon himself. Wheeler has suffered from angina pectoris for several years, having three or four attacks yearly, but always relies on the treatment prescribed by physicians for the relief of his attacks!

Following the hearing, Judge Karl A. Crowley, Solicitor for the Post Office Department, declared that Wheeler's scheme was one for "obtaining money through the mails by means of false and fraudulent pretenses, representations and promises." He recommended the issuance of a fraud order against "Clayton E. Wheeler, A.B., M.D., Dr. C. E. Wheeler, Dr. Clayton E. Wheeler, Dr. Clayton E. Wheeler, Surgeon, Clayton E. Wheeler, M.D." at San Francisco and Los Angeles. Acting Postmaster-General W. W. Howes issued such an order May 2, 1934.

Correspondence

A DEFENSE OF SUPRAPUBIC PROSTATECTOMY

In a recent contribution to THE JOURNAL (Young, H. H.: Transurethral Resection of the Prostate, THE JOURNAL, June 9, p. 1913) a slight error credits me with a death rate of 40 per cent following the operation of suprapubic prostatectomy. The error would not be worth comment had it not elicited from a number of kindly disposed urologists protests that exhibit a misconception of certain social phenomena that underlie the ancient dispute between the prostatectomists, perineal and suprapubic, as well as the modern antagonism between the champions of prostatectomy and those of prostatic resection.

Operations owe their initial vogue to advertisement. The adjective "conservative" attributed by Dr. Young to the operation of perineal prostatectomy, for example, conveys an aroma of sexual immortality most enticing to the aging male. In the history of prostatic surgery there have been a large number of operative procedures (most of them covering incompetence to do a successful prostatectomy) popularized through the enthusiasm of their originators. The medical journals of a generation ago tell us that castration was then an ideal! Thereafter came Bottini, Chetwood, perineal prostatectomy, the Young punch, and so on.

But, vain mortals, we do not report our failures! No one with a 40 per cent prostatectomy mortality will be rushing into print. We cease to perform those operations that give us bad results and often enough we find it untactful to publish any criticism of them. Thus castration, the Bottini and the Chetwood operations—not to mention the moribund—have died what might be termed a natural death.

Alas, it seems as though perineal prostatectomy, the most beautiful of all the prostatectomies, is also doomed! Surely no one would prefer a two-stage suprapubic prostatectomy, even the modern, clean operation, with its longer hospitalization and correspondingly higher mortality (for to Dr. Young himself we owe the observation that the senile prostatic must be got out of bed) to the beautiful dissection of which Dr. Young is master—except for the fact that in other than the most skilful hands the perineal operation is too uncertain. We present our regrets to Proust, to Albarran, to Wildbolz, to Hinman, to all the other honest gentlemen who have labored so well between "wind and water." They have opened a delightful operative field, which with the disappearance of perineal prostatectomy, vesiculectomy, radium implantation, threatens to become a lost region.

But prostatic retention must be treated by many surgeons who have not had the good fortune to learn or the constant opportunity to practice perineal operation with due respect for the rectum and for the sphincters. Such men must operate "above the bone." They must cling to that operation which alone provides fool-proof drainage; in which no slightest slip entails the dangers of rectal perforation, urinary dribbling, prostatic sepsis; and which gives an adequate insurance against pelvic infection.

Dr. Young mentions again (*loc. cit.*) his surprising record of 198 successive perineal prostatectomies without a death. Other operators, perineal, suprapubic, resecting, have usually stopped at 100 deathless cases, for there comes a time when one attempts too much and the record falls. The wise prostatic operator will do the best he can for each patient by whatever operation he prefers, considering what the patient's life will be worth to him if he survives, as compared to its worth without operation.

As a matter of fact, none of us operate on all our prostatic patients. Some of them escape operation to die of intercurrent disease, some die of their retention before operation is reached. Operative statistics are but part of the picture, sometimes an insignificant part except so far as they conserve our professional vanity. The social aspects of the disease are, on the contrary, of the greatest interest. What operation can best be done by the greatest number of operators? What should be our treatment for the wealthy, for God's friends, the poor?

My impression as to the answer to the first question has been suggested. Time will tell. But as to the second—which gets us back to the "40 per cent mortality"—I have more positive views. During the period in command of the Bellevue Hospital Urological service (1915-1924) I felt that the prostatics who entered that city institution, wrecked by privation and utterly bad risks as many of them were, should be afforded treatment that would send them out cured, if at all. They could not afford post-hospital care. Many of them had no families; many, indeed, no proper homes. To discharge them from the hospital with catheter or suprapubic tube seemed as pitiful as to send them forth dribbling or with a cloaca. A study of our Bellevue statistics led to the publication of "The Prospects of the Prostatic" (Keyes, E. L.: *Pennsylvania M. J.* 33:672 [July] 1930). Evidently our elucidation at that time was inadequate. We venture to try again.

THE PROSPECTS OF THE PROSTATIC WITHOUT OPERATION

The following data are from the case books of private patients treated by my father or by Dr. Fuller (and a few by Dr. Chetwood or myself) before 1900. Operations were few and performed only in advanced cases. The operative mortality was about one in three. (Freyer, passing his finger nonchalantly from rectum to suprapubic wound *but providing "stove-pipe" drainage*, was the first to bring the mortality of suprapubic prostatectomy within reasonable limits.) Our cases number about 240.

The expectation of life from the first symptom to chronic complete retention was

For patients under 50 years of age at onset.....	6 years
For patients between 50 and 60.....	4 years
For patients over 60.....	2 years

No attempt was made to estimate the expectation of catheter life. It seemed brief and miserable.

One hundred and twenty patients (about 50 per cent) had acute complete retention of urine at some time, and in about half of them this was the initial symptom.

Twenty-seven of these acute retentionists resumed approximately normal bladder function. They averaged 57 years of age at the time of the acute retention. This usually occurred within the year, though four patients insisted that they had gone ten years between retentions.

Fifty-seven went into incomplete retention. Their average age at the time of the acute retention was 60 years. The oldest of this group was 73.

Thirty-six remained in complete retention. The average age was 70.

These age differences are attributable rather to progressive weakening of the bladder muscle with age than to increasing size of the prostate. The rate of growth of prostatic hypertrophy varies greatly, but the gland seems usually to attain its maximum size at about the seventieth year. Conceivably sexual peace settles on it by this time—the palpable size of the prostate being dependent in some measure on congestion.

PROSTATIC MORTALITY BEFORE AND
AFTER PROSTATECTOMY

At the Bellevue Hospital between 1915 and 1924 there were eighteen operating surgeons on the staff, including the residents who were doing their first prostatectomies. The favored operation was two-stage prostatectomy, though many one-stage operations and a few perineal operations were done. As stated, every effort was made not to send the patients out with catheter or suprapubic tube. There were 175 prostatics—

- 175 prostatics
- 26 not operated on, of whom 14 were relieved and 12 died
- 98 suprapubic drainage, of whom 33 died and less than a dozen left the hospital with permanent drainage; the remainder had prostatectomy
- 110 prostatectomies, in which 40 died. (Is this the "40 per cent"?)

The total mortality at Bellevue, therefore, for eighteen operators, many of them beginners, and on the worst possible material, was 35 per cent for the prostatectomies and 49 per cent for the prostatics.

Six years passed before I could face publication of this record. Then, learning that in the city hospitals of two other large cities the prostatic (not the operative) mortality was, respectively, 45 and 47 per cent, and having got some notions that promised to better this sad state of affairs, I published the statistics together with a more recent series, consolatory in character, the work of myself and three other surgeons at St. Vincent's Hospital.

The patients in this St. Vincent's series were mostly private patients. Almost all were operated on by two-stage prostatectomy.

- There were 76 prostatics
- 10 were not operated on, of whom 3 died and 7 left the hospital relieved
- After suprapubic drainage 4 died and 1 refused prostatectomy
- 61 prostatectomies resulted in 53 cures, 5 partially relieved, 3 deaths

This brief series can therefore be reported as showing 5 per cent prostatectomy mortality, or 14 per cent mortality among prostatics, or as 70 per cent cures; 10 per cent left the hospital and 10 per cent died before prostatectomy; 10 per cent died or were not wholly relieved by prostatectomy.

"The Prospects of the Prostatic" achieved its purpose of drawing attention to the prostatic problem. Dr. Stevens has markedly improved the prostatic prognosis at Bellevue. He has kindly permitted me to publish his results for 1926-1934. They are as follows:

- 813 prostatics, of whom 188 (22.6 per cent) died
- 614 were operated on, of whom 131 (21.3 per cent) died
- 199 were not operated on and 57 died shortly after admission
- 56 had only a vasotomy, of whom 27 died
- 15 perineal prostatectomies, after which 3 (20 per cent) died
- 208 one-stage prostatectomies, after which 19 (9.6 per cent) died
- 272 suprapubic cystotomies, after which 60 (22 per cent) died and
- 33 returned home, while:
- 172 had suprapubic cystotomies, of whom 19 (10 per cent) died

In the year 1931 I published a technic for two-stage prostatectomy, recording 113 prostatectomies (personal) with 6 (5 per cent) deaths (Keyes, E. L.: The Preventable Infections Incident to Preparing for Prostatic Operations, *New England J. Med.*, 204:906-910 [April 30] 1931). Beer has noted that the

5 per cent mortality in his clinic is not far from the normal expectancy.

With clean suprapubic wounds our results both as to stay in the hospital and mortality are constantly improving. We can now teach prostatectomy without disaster. My associate Dr. McLellan has performed his first thirty-four two-stage prostatectomies with one death due to cancer of the rectum.

Upon this harmony irrupts the criticism of Dr. Young:

With the passage of time the ultimate mortality of the suprapubic route has been shown to be much too high. The preliminary cystotomy alone has presented a sizable mortality. Keyes has frankly acknowledged a mortality of 40 per cent in his series of suprapubic prostatectomies. . . .

We feel he leaves a false impression.

EDWARD L. KEYES, M.D., New York.

[The statement by Dr. Keyes was referred to Dr. Hugh H. Young, who replies:]

To the Editor:—When I stated that Dr. Keyes' mortality was 40 per cent, I was in error, and I apologize. I should have said his clinic, as he states that "in a hospital in which a series of patients operated upon under my eye by 18 different surgeons, there were 175 patients, chiefly operated upon by two-stage prostatectomy and 85 (49 per cent) did not leave the hospital alive. Among these 26 were not operated upon, and 12 died. Ninety-eight were drained suprapubically and 33 died. One hundred and ten prostates were removed with 40 deaths." Again, in his textbook, he states, "In free city hospitals . . . the total mortality approaches 50 per cent." In another paper he says, "At Bellevue Hospital . . . the mortality is 49 per cent."

Dr. Keyes says, "Dr. Young mentions his surprising record of 198 successive perineal prostatectomies without a death. Other operators . . . have usually stopped at 100 deathless cases. . . . The wise operator will do the best he can for each patient . . . considering what the patient's life will be worth to him, if he survives, as compared to its worth without operation."

The suggestion is that I picked my cases so as to avoid mortality. Dr. Lloyd G. Lewis has assisted me in studying again the period between Feb. 20, 1919, and Sept. 18, 1922, during which I carried out 198 perineal prostatectomies without a single death, all patients leaving the hospital. Eighteen were between 75 and 85 years of age; ninety-eight had cardiac disease. We found that during this period there were nine of my patients who were not subjected to prostatectomy. Eight of the patients received no operative treatment. Three left to be operated on at home. The fourth, aged 82 years, senile, had a bad heart and kidneys and was sent home to die in a few days. The fifth had dementia and had only slight prostatic obstruction; he was consigned to the psychiatric department. The sixth was one whose symptoms were so slight that no operation was advised. The seventh and eighth died of uremia, and autopsy showed pyonephrosis. Another severely ill patient had suffered false passage of a catheter before admission. Suprapubic cystostomy for drainage was carried out. He died ten days later, and autopsy showed abscesses, retrovesical and renal. This total of 207 cases of benign prostatic hypertrophy represents all of my own patients who were in the hospital during this period. Among the 207 cases there were three deaths (1.4 per cent).

During the same period of two and a half years, 269 cases of prostatic hypertrophy were admitted to the public wards and the private services of the three other members of the visiting staff. Of these, 257 patients were subjected to perineal prostatectomy by eighteen different operators, with twelve deaths (4.7 per cent). Three had suprapubic cystostomy for drainage with no deaths. Ten received no operative treatment, with six deaths. These were cases that failed to respond to

preliminary treatment. Therefore, among the total number of "prostatics" (269 cases) cited there were eighteen who died, a total mortality of 6.6 per cent. It is interesting to note that the number of surgeons was the same as the eighteen referred to by Dr. Keyes, "who operated under his eye" on 110 patients by suprapubic prostatectomy with forty deaths, and that the total mortality for the 175 "prostatics" was 49 per cent.

If public ward patients operated on by the visiting staff are excluded, during this period ninety-two public ward patients were operated on by fifteen residents, assistant residents or interns, with four deaths, a mortality of 4.1 per cent. In addition, they performed two suprapubic prostatectomies with no deaths. There were six public ward patients too ill for operation, and four of these died. If these are added to the record of the residents, the total of these public ward "prostatics" admitted during this 2½ year period is, therefore, 100, and the total number of deaths eight, or 8 per cent, as compared with the 49 per cent reported by Dr. Keyes.

It is only fair to state that I have had "unlucky" periods with a varying mortality. In a twenty year period that was carefully studied (Young, H. H.: *Surg., Gynec. & Obst.* 36: 589 [May] 1923) I performed 1,049 perineal prostatectomies with a mortality of 3.4 per cent. Fifty per cent of these patients had some form of cardiovascular disease, and 144 were between 75 and 95 years of age.

Dr. Keyes remarks: "The beautiful dissection of which Dr. Young is master . . . in other than the most skilful hands, the perineal operation is too uncertain." Thanks, but why too uncertain for any but the "most skilful hands?" Our fifteen residents and interns, doing their first work on the prostate, had a mortality of 4.1 per cent, as already referred to.

Again: "They [the surgical profession] must cling to that operation which alone provides fool-proof drainage, and in which no slightest slip entails the dangers of rectal perforation, urinary dribbling. . . ." In 1,264 operations by nineteen operators there have been nine rectal injuries (0.7 per cent), hardly enough to be a bugaboo. Surely the up-hill suprapubic drainage is no more fool proof than the down-hill perineal route, which drains the prostatic cavity directly to the outside. In fact, it is one of the great reasons why perineal prostatectomy is safer than the suprapubic. If suprapubic drainage is fool proof, how about its 33 per cent mortality in the ninety-eight cases he reports? As to dribbling: In 450 cases of perineal prostatectomy, I found only three cases of incontinence (Young, H. H.: *The Ultimate Results of Prostatectomy*, Memoirs and Bulletins of the International Congress, London, 1911).

Again, "Alas, it seems as though perineal prostatectomy, the most beautiful of all the prostatectomies, is doomed!" The perineum "threatens to become a lost region" to surgery. "Prostatic retention must be treated by many surgeons, who have not had the good fortune to learn . . . the perineal operation. . . . Such men must operate above the bone."

If perineal prostatectomy is doomed, along with it will go other perineal operations, such as those for cancer of the prostate, stones in the prostate, ruptures of the prostatic urethra, cysts of the prostate, abscesses and tuberculosis of the prostate and seminal vesicles, and many other rarer conditions, which can be accurately attacked only through the perineum. Is the radical operation for carcinoma of the prostate, by which over 50 per cent of the cases have been cured, to be given up? Are surgeons to leave unaided those extensive cases of genital tuberculosis, with involvement of the seminal vesicles and prostate, a considerable percentage of which have been cured, even though it was necessary to remove also the kidney in one third of the cases? Are those young men, carrying hundreds of stones in the prostate, and with grave symptoms, both local and sexual, to be left in their misery,

simply because the surgeon unblushingly states that the perineum is for him a terra incognita, and that he is unable to master the anatomy and physiology of this region, which many a hospital intern has learned without much difficulty? Should the surgical profession, because of ignorance or ineptitude, give up perineal prostatectomy, "the most beautiful of all prostatectomies" according to Dr. Keyes, regardless of the fact that it has been conclusively shown, not only by studies of the records of eighteen operators in my service, but also by the reports of Cecil, Hinman, Davis, Deming, Phifer, Wildbolz and others that the mortality is much less than that reported by Dr. Keyes? Should not every urologist pretending to competence in all urologic surgery be the master of the perineum, through which alone so many diseases can be attacked?

Why this constant reiteration of the difficulties of the perineal route? The technic is not only "beautiful" but indeed simple. The principal requisites are that the patient be in a proper position, with the pelvis flexed, the perineum elevated, so that the operator may see every step of the operation; that the central tendon be isolated by blunt dissection on each side, and that it be divided well away from the rectum, which should be constantly visible; that the recto-urethralis muscle be isolated, picked up with forceps and divided close to the membranous urethra, well away from the rectum, under visual guidance. The operator should then divide the posterior layer of Denonvilliers' fascia close to the apex of the prostate and then push it backward, carrying with it the rectum, which is thus efficiently protected by this strong fascia. If this technic is followed, there is practically no danger of injuring the rectum. The external sphincter can thus be avoided, eliminating incontinence. For these reasons I dubbed my operation "conservative," and because the ejaculatory ducts were avoided. Dissection between the two layers of Denonvilliers' fascia separates not only the prostate but also the seminal vesicles and ampullae of the vasa deferentia from the rectum, thus making not only conservative perineal prostatectomy but also the radical operation for cancer, and total extirpation of the vesicles, vasa deferentia and lateral lobes of the prostate for tuberculosis easy to perform without any danger of injuring the rectum. It is only necessary for the surgeon to have anatomic knowledge and good eyes to recognize the surgical landmarks, muscles and fascia, and that he have sufficient pride to avoid inexcusable mistakes. It is wise for all surgeons, before attempting operations through the perineum, to practice on the cadaver. This should give the knowledge and skill required for accurate operative technic.

As noted in the statistics, suprapubic drainage is rarely employed. A retained catheter is usually sufficient. Urethrotomy through the bulbous urethra is a safer substitute for suprapubic drainage, which, Dr. Keyes has shown, is accompanied by so high a mortality. With proper care the urethral catheter is usually entirely satisfactory.

The principal factors in the safe treatment of "prostatics" are:

great care in preoperative treatment and instrumental study in each case; gradual decompression, by which immediate emptying of overdistended bladders, so often accompanied by collapse, uremia and early death is avoided; forced internal hydrotherapy and appropriate cardiovascular therapy to stimulate renal function; accurate knowledge of the conditions present by phenolsulphonphthalein tests, blood chemistry, cystoscopy, and other means; continuation of the preoperative treatment until renal and cardiovascular studies indicate that the optimum of improvement has been reached, and operation may be carried out as safely as possible; the use of intravenous therapy—salt solution or dextrose to stimulate renal function, and 1 per cent mercurochrome in 12 to 15 cc. doses into the veins, to combat septicemia; the early removal of all packs and tubes from the wound, which is frequently lavaged with mild antiseptics, such as boric acid and mercurochrome; the avoidance of urethral instrumentation (if possible) during convalescence.

It is by the gradual development of these safeguards that the low mortality of perineal prostatectomy, even in serious cases, has been attained. Such results with perineal prostatectomy are not solely attainable by one institution and its graduates but can be accomplished by all who take the proper interest, time and trouble to learn the anatomy and the operative technic of the perineal route, and the laboratory and clinical studies that insure success. These comments apply also to those who have deserted suprapubic prostatectomy to take up transurethral resection, even in large hypertrophies, manifestly an incomplete operation in such cases.

HUGH H. YOUNG, M.D., Baltimore.

SURGICAL TRADE CODE FORBIDS REBATES

To the Editor:—As secretary of the American Surgical Trade Association, which sponsored the Code of Fair Competition for the Surgical Distributors Trade, approved on Aug. 24, 1934, I wish to call the attention of the members of the medical profession to certain provisions of this code, which are of special interest to members of the medical profession.

This code contains the trade practice provisions prohibiting what is generally called commercial bribery which are found in almost all codes of fair competition. These provisions are contained in section I of article VIII of the Code of Fair Competition for the Surgical Distributors Trade and read as follows:

Section 1. No member of the trade shall give, permit to be given, or offer to give, anything of value for the purpose of influencing or rewarding the action of any employee, agent or representative of another in relation to the business of the employer of such employee, the principal of such agent, or the represented party, without the knowledge of such employer, principal or party. Commercial bribery provisions shall not be construed to prohibit free and general distribution of articles commonly used for advertising except so far as such articles are actually used for commercial bribery as hereinabove defined.

At the public hearing at Washington, D. C., before the deputy administrator assigned to this code, the giving of commissions to physicians for referring patients to surgical appliance dealers was discussed at length. It was the consensus of those discussing the practice that the giving of commissions to physicians added to the cost to the patient of such articles: that such patients are generally of limited or no earning capacity and that such practice was probably the most indefensible form of commercial bribery.

While probably the general prohibition of commercial bribery covers the giving of secret commissions to physicians, so as to remove any doubt on this point a specific provision was placed in the section on commercial bribery of the Surgical Distributors Trade Code declaring that physicians offering or recommending to their patients the purchase of products of the trade are the agents of their patients. This provision of the code is as follows:

For the purposes of this Section, physicians, surgeons, and other professional men and women shall be considered agents or representatives of their patients and/or clients when they offer or recommend the purchase of products of this trade.

The Code of Fair Competition of the Surgical Distributors Trade, therefore, makes a practice which was previously highly unethical now unlawful and punishable by a fine of \$500 for each violation under the provisions of the National Industrial Recovery Act.

I ask your aid in bringing this provision to the attention of the medical profession as widely as possible so that there will be no violation of this provision of the Code of Fair Competition of the Surgical Distributors Trade through lack of knowledge on the part of members of the medical profession.

FRED B. HOVEY, Chicago.

Secretary, American Surgical Trade Association.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SNAKE-BITE

To the Editor:—Are poisonous snakes known to live in New Jersey near the Delaware Water Gap and in New York in the Catskill Mountains? Is antivenom serum effective? What firm produces the most reliable serum? What animals are used to produce antivenom serum? This is important for anaphylaxis; I have in view a family sensitive to horse serum. Please omit name.

M.D., New York.

ANSWER:—In both places, the timber rattlesnake and the copperhead are found. In case of snake-bite, local treatment should first be given. A tourniquet is applied, not too tightly, above the site of the bite and should be moved upward as the swelling spreads. Short cross-shaped incisions are made at the site of the fang marks and others an inch apart around the edge of the swelling. As the swelling spreads, further incisions are made. Suction is applied to these incisions, either by a suitable mechanical apparatus or by the mouth, if this is free from sores. Venom is not absorbed from an intact mucous membrane and is destroyed in the stomach if swallowed. The suction is continued for fifteen minutes and repeated at hourly intervals for several hours. The wound must be carefully covered between times with a clear cloth or gauze soaked in 2 per cent salt or epsom salt or an antiseptic that does not coagulate albumin. A physician or hospital should be reached as soon as possible. Violent exercise, even fast walking, and alcoholic stimulants are to be avoided, as they increase the rate of absorption of the poison.

Antivenin is injected as soon as the local treatment is initiated. Not less than the full contents of one syringe should be given at once and, in case the snake is large or the victim is a child, two or more should be given immediately. About half of the dose is injected subcutaneously in a ring about the local swelling, to antagonize the local effects of the venom; the remainder in a muscle high up on the bitten limb or subcutaneously over the abdomen or between the shoulder blades. If constitutional symptoms are not relieved within an hour, further injections of antivenin should be given as indicated.

Antivenin against the bites of North American snakes is made by the Mulford Biological Laboratories, Sharp and Dohme (Glenolden) Philadelphia, supplied as Antivenin (Nearctic Crotalidae) or North American Anti-Snakebite Serum. It is prepared only from horse serum. It is a polyvalent antivenin, prepared against the venoms of all the poisonous snakes of North America, except the unimportant coral snake. It is effective if given in adequate dosage. From one to four syringes will be sufficient in most cases for such poisonous snakes as occur in the northern part of this country.

INJECTION OF VARICOSE VEIN

To the Editor:—About three months ago, I had injected 3 or 4 minims (0.2 cc.) of 5 per cent sodium morrhuate into a leg vein, when the vein suddenly disintegrated, allowing the solution to become free in the tissues. The patient had so much pain that she refused to allow any protective measures. Since then an excruciatingly painful ulcer has formed, which refuses to heal. The patient says it is more painful and troublesome than the four year old varicose ulcer which I did succeed in closing. Please advise on the treatment of this obstinate ulcer. Also give pointers on the prevention of such an accident and the steps to be taken at the time of such a rupture. What can I do for the extreme pain locally? Please omit name and address.

M.D., New York.

ANSWER:—From the description it is not quite clear whether the injection of sodium morrhuate was deposited outside the vein or whether an actual necrosis of the wall of the vein took place at the site or at some distance from the injection. The latter mishap does not occur suddenly but several hours or days after the injection. When the patient complains of a sudden pain during or right after the injection, the solution in all probability is deposited in or outside the vessel wall. In such an event it is wise to stop further injections immediately and inject 5 cc. of blood taken from an adjoining vein into the area of skin, which blanches and balloons out. A protective dressing is applied and an electric pad is used to hasten absorption of the hard mass. Should the skin break down, an immediate excision not only of the ulcer but of the entire indurated mass results in a primary union. When excision is delayed until secondary infection takes place, this must first be cleared up by hot boric acid dressings and immobilization. One per cent nupercaine ointment may alleviate the pain. The success of complete excision and primary closure requires surgical experience and may necessitate skin grafts.

ARTHRITIS WITH DIABETES

To the Editor.—I have a diabetic patient, a man, aged 62, who has an acromioclavicular bursitis (left) and a neuritis involving the left upper extremity. The neuritic symptoms began about four months ago and disappeared under treatment with sodium salicylate and control of the diabetic condition. About one and one-half months ago the patient fell on his left shoulder. Since that time he has complained of severe pains in the left shoulder, forearm and wrist and at the insertion of the deltoid, and sensations of pins and needles in the finger tips. The pains travel from one place to another. There is marked limitation of motion of the shoulder because of pain. The patient describes the pain in the arm and forearm as a continuous gnawing and drawing sensation. When heat from a therapeutic lamp is used the pain almost ceases, but it returns as soon as the heat is removed. The pain is so severe and annoying that only about one to two hours of sleep is gotten at night and that is due to the use of strong narcotics, as pantopon and morphine sulphate. Iron cacodylate intravenously (five doses) and diathermy treatments over a period of three weeks gave no results. On one occasion partial relief from the gnawing pain was obtained by the use of sodium salicylate, 10 grains (0.65 Gm.), acetylsalicylic acid, 5 grains (0.3 Gm.), amidopyrine, 3 grains (0.2 Gm.), and codeine, one eighth grain (0.008 Gm.), every two hours as required. The relief lasted during the period of medication, but when the symptoms of overdosage (ringing in the ears) developed, medication was stopped and the pain returned. Roentgen examination reveals a small amount of calcification of the bursa. Do you think that nonspecific protein injections such as intravenous administration of typhoid vaccine would be of help, considering the age of the patient? What treatment would you advise and what is the prognosis? At this time the diabetic condition is uncontrolled. There is a small amount of atrophy of the muscles in the arm which I think is due to nonuse. Sensations are normal, the neurologic examinations are negative. As I have stated, the salicylates relieved the neuritic pain for one day, but the pain in the shoulder due to the bursitis was not affected. It seems that the neuritic pangs are the ones that prevent sleep. The electrocardiogram gave no evidence of coronary disease, there was a left ventricular preponderance. The roentgen examination of the spine was negative. Please omit name.

M D, New York

ANSWER.—The appearance of arthritis in patients with disturbed sugar metabolism is interesting and the relation of the two conditions is unknown. The diabetes must be kept under control. Osteo-arthritis involving the cervical spine, especially the fifth and sixth vertebrae, is not always demonstrable by roentgen examination, especially in the early stages. There may be an exudate in the vertebral foramina caused by pressure on the spinal nerve roots.

The treatment includes a combination of factors that may be effective. Vaccines are worth trying and should be given in small doses at intervals of from four to five days, until the pain is under control. All drugs except codeine by mouth or salicylates in large doses by rectum should be stopped.

In the treatment of this case the application of heat and arm traction should be considered. If this is unsuccessful, gentle manipulation under ether anesthesia following gas induction should be done. Physical therapy, including radiant heat, gentle massage and diathermy should follow. If diathermy exaggerates the symptoms, it should be discontinued.

STERILITY

To the Editor.—A woman, aged 36, in good physical condition, married five years, conceived first in 1930 and aborted ten weeks later. She aborted again the following year and since then has failed to conceive altogether. The Rubin test was done on two occasions and was found negative. The husband is highly emotional but otherwise in good health. Semen examination under a slide shows active spermatozoa for over two hours. It may be important to add that the woman received a curettage after the first abortion but not after the second. What would be the rational procedure in such a case? Would it be worth while to try artificial impregnation? What knowledge can be obtained from a morphologic study of the spermatozoa? How is such a specimen prepared? Kindly omit name.

M D, New York

ANSWER.—No information is given concerning the condition of the pelvic organs. Not infrequently in such cases there is a hypoplasia of the uterus. In some of these patients, injections of anterior pituitary hormone and thyroid preparations prove helpful. It is assumed that by a "negative" Rubin test the inquirer implies that the tubes are patent to gas. If the tubes are impermeable, artificial impregnation should not, of course, be considered. A good deal of information can be obtained from a careful study of the spermatozoa. Excellent articles on this subject have been published by G. L. Moench (*Am. J. Obst. & Gynec.* 25:410 [March] 1933; *J. Lab. & Clin. Med.* 17:297 [Jan.] 1932). Most likely some spermatozoa are capable of fertilizing an ovum but are incapable of producing a full term child. Unfortunately there is as yet no way of detecting such defective spermatozoa. A curettage is not essential although, as most physicians know, pregnancy not infrequently follows a dilation and curettage. If the spermatozoa appear normal and the tubes are patent, the contents of the cervical canal should be aspirated after coitus to see if there are actively motile sperm in and beyond the cervix. Not infre-

quently, normal spermatozoa fail to traverse the cervical canal. In such cases, if the cervical secretion cannot be altered by treatment, artificial insemination should be tried. This should be carried out under aseptic precautions a few times during each midinterval between menstrual periods. The patient and her husband should be informed that many inseminations will most likely have to be made.

ACNE OF EXPOSURE TO CHLORINE

To the Editor.—A white man, aged 25, single, in perfect health until eight months ago, has worked for several years in a chemical plant in which a dye for rayon is manufactured, this is called Aocolor-1169. The present illness began eight months ago, at which time acne developed on the back of the neck, along both arms and over the entire back. This condition has become progressively worse, so that the entire area is covered with red nodules just beneath the surface of the skin. Apparently these areas are small cysts, as they contain cystic material, which then become infected, with the formation of pus. Culture shows a mixed group of organisms; biopsy confirms it. In the preparation of Aocolor 1169 the following chemicals are used: hydrogen, benzene, chlorine gas, hydrochloric acid and gas. It is called a di phenyl process. To date, the following treatments have been used with little success: x rays, autogenous vaccine, incision of the small abscesses followed by swabbing with phenol (carbolic acid), painting with gentian violet, acriflavine hydrochloride and mercurochrome, and covering with irradiated petrolatum. Could you possibly suggest something else or some reference that might be of help, also some explanation as to the cause of this condition? Kindly omit name and address.

M D, Georgia.

ANSWER.—The description furnished is regarded as that of "chlor-acne." The inclusion of chlorine gas in the listing of chemicals utilized in the manufacturing process furnishes the probable causative agent. So long as exposure is perpetuated, the condition probably will persist. The well established case, even after further exposure is terminated, is subject to the well known vicissitudes attending acne treatment. Since exposure has been terminated, as good results are to be expected from the general line of treatment specified in the query as from any other form of treatment. Possibly something may be gained by the use of a diet low in carbohydrates. Apart from the already established case, control is linked up with prevention. In the workroom wherein this condition probably was incurred, such devices and measures should be instituted as will eliminate exposure to such substances as benzene, chlorine gas and hydrochloric acid. Additional comment may be found in Prosser White's "The Dermatogoses."

USE OF SODIUM HYPOCHLORITE FOR WOUND IRRIGATION

To the Editor.—Will you please give me the correct technique for using sodium hypochlorite solution in the irrigation of infected wounds. Please do not print my name.

M D., North Carolina.

ANSWER.—Physiologic solution of sodium hypochlorite should be made according to the method described in the U. S. Pharmacopeia under *Liquor Sodii Chloridi Physiologicus*. A solution somewhat similar to the U. S. P. preparation may be made by diluting the proprietary preparation *Hyclorite*, which has been accepted for inclusion in New and Nonofficial Remedies.

A preliminary cleansing of the skin and wound is necessary. Excision of all lacerated or devitalized tissue should be done. All pockets of the wound should be explored and Carrel rubber tubes introduced for instillation of the solution. Ordinarily counter drains are not required.

The drainage tubes are of fine pure rubber approximately 15 to 25 cm. long having a diameter of 5 mm. and a lumen of 3 mm. The ends are tied off with linen or silk, and beginning at the distal end from six to twelve small holes approximately 0.5 mm in diameter are pierced at intervals of 0.5 cm. These may be made with a special punch, the two sides being pierced at the same time and the direction being staggered.

The number of tubes used must be decided by the size and depth of the wound. All parts of the wound should be bathed by the solution coming out of the tubes. To prevent the tubes from bunching in the wound, strips of gauze are placed between them, which helps also to retain the solution.

For superficial wounds the Carrel tubes are covered with Turkish toweling, and strips of gauze are placed between the tubes. A large pad of nonabsorbent cotton may be placed around the extremity. Simple wet compresses are sometimes used and changed frequently in superficial wounds.

The skin should be protected by covering with strips of gauze impregnated with petrolatum.

Intermittent irrigation every two hours day and night with just enough solution to fill the wound has been most satisfactory. This is not always possible, and good results may be

obtained by less frequent irrigation, although it is not so efficient in sterilization.

The wounds should be redressed daily, the skin being cleansed and the tubes renewed. In certain conditions the change of dressings may be delayed for two or three days, provided the irrigations are kept up.

Bacteriologic films are made of the wound discharge from day to day and, when sterile, deep wounds may be sutured.

CHRONIC PROSTATITIS

To the Editor.—Four months ago a patient, aged 55, experienced discomfort in the perineal region, especially when sitting. This discomfort he compares to a sensation of two raw surfaces in contact with an anterior rectal wall. At times there is a sensation of distention in the scrotum. Eighteen months ago he was treated for a small ulceration on the verumontanum. Examination of the prostate reveals a normal sized left lobe and median bar, but the right lobe is slightly enlarged. The entire gland was somewhat hard but rather smooth, and a tenderness was elicited by massage. The prostatic secretion, after massage, showed a moderate number of pus cells. There has been no difficulty in urination and no retention. Examination of the scrotum shows a small varicocele. Examination reveals no hemorrhoids or rectal pathologic changes. A urologist made a cystoscopic examination and found no pathologic change other than some enlargement of the median bar. I began treatment by passing a number 26 sound every ten days, massaging the prostate twice weekly and applying infra red rays to the perineum. A small amount of improvement was noted at intervals during the first two months. The treatment was continued until three weeks ago, when I began giving the patient intramuscular injections of Proteolac (Searle). A dosage of 5 cc. was used for the first three injections at intervals of four days, then 10 cc doses were given at the same intervals. Today he received his seventh injection. I have massaged his prostate on the days when he has received injections. No relief has been noted, except on one occasion five days ago, following a sounding, massage and an injection of proteolac. A smear of the prostatic secretion one week ago showed numerous pus cells. The treatment has not cleared the secretion of pus cells or given the patient permanent relief. Potassium iodide and bromides have been prescribed with no benefit. Please advise me as to the possible cause and the treatment of the patient's discomfort. I have made a diagnosis of chronic prostatitis.

M. D., Kansas.

ANSWER.—The diagnosis of chronic prostatitis seems correct in view of the symptoms given and the physical changes found. The fact that there is some hypertrophy of the median bar would indicate prolonged inflammation. Patients with chronic prostatitis that remains so resistant to the usual forms of treatment will frequently, with a more careful study of the posterior urethra, be found to have deep seated small prostatic abscesses. These drain through what appear to be dilated prostatic ducts and can at times be seen to exude thick, purulent material. The openings of these ducts are usually located just lateral to the verumontanum, toward the bladder sphincter.

Treatment should consist of dilation of the openings of these ducts with a blunt instrument such as a stiff electrode to secure freer drainage of the small pockets of pus. If these pockets are deeply situated, it may be necessary to enlarge the openings by incision with the Collings electrode. The incision should be carried through the sphincter and median bar in much the same way that an incision is made through the rectal sphincter in treating fistula in ano. If the median bar enlargement interferes with proper drainage, the walls of the incision should be cut away so that when the patient voids, the urine washes out the contents of these abscess pockets. The fact that the verumontanum remains enlarged and inflamed is another indication that chronic infection of the described type is probably present.

Intravenous and oral medication is usually of little avail in this type of case, in which the chronic inflammation persists because of the factor of faulty drainage.

BILATERAL ITCHING OF EARS

To the Editor.—A patient, aged 40, a married woman, in good health, has been troubled for one year with intensive bilateral itching of the external auditory meatus and auricle. In the beginning, an acute eczematous condition was present, but now there is only a slight red induration. The usual ointments for eczema, stimulating and soothing, with and without phenol, have been tried, with very little effect. The itching is present every day and is so intense that the patient seems completely unable to resist scratching it. There is no history of frost-bite or anything that would appear to be an etiologic factor. Can you suggest additional treatment?

MALCOLM B. WILCOX, M.D., Holdrege, Neb

ANSWER.—The problem in the case cited is to reduce itching to the point at which the patient can resist the temptation to scratch, then to increase her self control and break the habit of scratching. Two methods suggest themselves. The patient may be given a general sedative such as bromides, which will make her less nervous and make it easier to resist scratching. The danger of skin eruptions from bromides, which restrains

many physicians from their use in similar cases, is much less than from the newer sedatives which have so largely supplanted the bromides, and is slight for short courses of medication. The intake of chlorides should be reduced as much as possible to facilitate the absorption of the bromides. After the soothing effect has been obtained, the dose can be reduced to three-fourths the amount and maintained for a week or two. A simple soothing ointment, as zinc oxide ointment or zinc oxide paste, should be applied once or twice a day. Only oil should be used for cleansing. Careful abstention from scratching should be insisted on.

Roentgen rays may be used to good advantage to the extent of two full erythema doses. This dosage should not be exceeded. One-fourth erythema dose, unfiltered or through a light aluminum filter, should be given once a week until the itching ceases. This often gives permanent relief. Cessation of scratching is as important as it is with the other plan of treatment.

ADDICTION TO BARBITAL

To the Editor.—I am interested to know whether you have any further data on amytal compound, sodium amytal and pentobarbital sodium as to their being habit forming or causing any undesirable after-symptoms. My reason for inquiring is based on a case, the history of which is as follows. A man about 50 years of age had been addicted to the use of morphine off and on for many years. He gave insomnia as the original cause for the addiction. He seemed to be in fairly good condition when he came to me one year ago after having been taken off the morphine habit one month before. He was suffering at this time with extreme insomnia, spasms and drawing of the muscles, and he was nervous and despondent. I started him on treatment with amytal in large doses, three capsules of sodium amytal, three capsules of amytal compound and three capsules of pentobarbital sodium (Abbott) given in two doses at 7 and 10 p. m. This seemed to give him instant relief with good nights of six to eight hours' sleep and very little after-effects in the morning. This was continued for six months, at which time he started to lose steadily in weight from 185 to 150 pounds (84 to 68 Kg.). Also suffering from chills and headache from early afternoon until time for his first dose of medicine, again he would be free from these disturbing factors as if by magic. These symptoms have been increasing in severity and it is with difficulty that he can be held off until time for the first dose of medicine. Please give me your most sincere judgment as to whether or not this medicine would be habit forming under these circumstances and if it would cause any of the symptoms I have referred to in this letter. I have had blood tests, that is, sugar, nonprotein nitrogen, Wassermann, red and white blood cell counts, roentgenograms of the lungs, a heart and a gastric series and cannot find any cause for the symptoms. This case is a most unusual one and I am anxious to know whether the medicine has played any part in these symptoms. Please omit city and name if printed in THE JOURNAL.

M. D.

ANSWER.—Addiction to barbituric acid derivatives is mentioned in Seifert's Nebenwirkungen der modernen Arzneimitteln, although this is not specifically described for amytal or for pentobarbital. Habituation to amidopyrine (a constituent of "amytal compound") has also been observed. The reaction described is probably caused by addiction to any one or all of the three compounds administered. This may be determined by separate administration of each of the three substances, with observation of the degree of relief of symptoms at each trial.

PILONIDAL CYSTS AND SINUSES

To the Editor.—Will you kindly let me know the frequency of occurrence of pilonidal cysts, also whether anyone has reported on the frequency with which they occur in mental defectives and whether or not their occurrence has ever been regarded as one of the stigmas of degeneracy.

C. STANLEY RAYMOND, M.D., Wrentham, Mass

ANSWER.—It is generally agreed that the pilonidal sinus or cyst is of congenital origin.

The site of the sinus, which usually produces symptoms in early adult life, is frequently marked by a dimple over the sacrococcygeal region seen in infancy. The occurrence of this dimple in infants and children under 4 years of age has been reported at from 20 to 39 per cent and in adults at from 4 to 30 per cent. Sinuses or fistulas have been found in 36 per cent of infants in 300 consecutive births. The occurrence of the sinus in the hospital records may be seen from the Massachusetts General Hospital, where 119 patients were admitted during eight years. Eighty per cent of these were males, in which it occurs more frequently. Some believe that there is a distinctive individual type in which this condition is most frequently found, characterized by obesity, hairiness and glandular dysfunction. There may be a familial tendency. The most support is given to the theory that this sinus is the result of a malfusion of the inferior end of the neural canal with its attachment to the skin. Others believe it is a faulty coalescence of the midline, a sequestration dermoid, or a traction dermoid fistula by a pull of the underlying tissue on the median

raphe. Recent support to it arising as a remnant of the preen gland in many birds is of interest. No figures have been found as to its occurrence in mental defectives or in persons with other physical anomalies.

EMBOLUS AND THROMBUS

To the Editor—Please be kind enough to differentiate between an embolus and a thrombus. The patient is presumed to have a mural thrombus following a coronary occlusion, which on breaking loose plugs the popliteal artery at the junction of the anterior tibia. Is the resulting obstruction an embolus, an embolic infarct or a thrombus? After amputation of the leg above the knee, the vessel in the amputated part is opened and traced. In the popliteal artery at the junction of the anterior tibia is an old organized drab colored fibrous obstruction giving evidence of having existed for several days. It is adherent to the vessel wall. Higher up in the popliteal artery at approximately opposite the knee joint is evacuated a black clot, soft, which is emptied out of the vessel easily, retaining its form and having on it projections that lead into small branches. The clot at the anterior tibia is presumed to have occurred first, and the second one the result of obstructed circulation below. What do you call them in their relation to the mural thrombus?

H. R. SUGG, M.D., Clinton, Iowa

ANSWER—An embolus is an insoluble foreign body free in the blood stream, which it may obstruct when impacted in its channel. A thrombus is a blood clot, in the heart or blood vessels, which remains at the site of its formation. Basing the answer on the correspondent's presumption, the resulting obstruction is an embolus. The mural thrombus, which is assumed to have occurred in the left cardiac ventricle following the coronary occlusion, was detached as a whole or in part, becoming an embolus. The embolus lodged in the popliteal artery at its junction with the anterior tibial and was found as the "drab-colored obstruction." The soft black clot is a propagated thrombus formed in the stagnant blood proximal to the embolic obstruction in the popliteal artery.

ORDER OF PROPHYLACTIC VACCINATIONS AGAINST INFECTIONS

To the Editor—In THE JOURNAL, April 21, page 1326, in answer to a question concerning the timing of immunization against infectious diseases, you recommend immunization against whooping cough. May I ask whose product you recommend, if it is on the market? Will you also please state the dosages and time intervals? Further on in the answer you state that the Schick test should preferably be performed in the spring or autumn. Will you please state the reasons? Kindly omit name.

M.D., Ky.

ANSWER—Among others, the pertussis vaccine (Sauer) prepared by Eli Lilly & Co. may be regarded as reliable. The dosage, which is given on the package, is 1 cc. subcutaneously in the upper deltoid region of each arm, followed in one week by 1.5 cc. subcutaneously in the biceps region of each arm and one week later by 1.5 cc. in the triceps region of each arm.

It should be noted that in the answer referred to it is stated that the Schick test should be made four months or more after a single injection of alum toxoid against diphtheria. This test is made in order to determine whether the child gives a negative test, that is, whether it is protected against diphtheria, and that in any case smallpox vaccination may now be done. It may be of advantage to vaccinate against smallpox in the spring so that the child may be protected during its wanderings in the summer; and the autumn is a good time for vaccination against smallpox in order to protect the child, as it may enter school then.

THERAPEUTICS OF THEOBROMINE

To the Editor—1. Are the diuretic effects of theobromine alkaloid more pronounced when given intravenously than when given by mouth? Give low and high limits of dosage for intravenous use. What are the symptoms of overdosage? 2. What is the relative efficiency of theobromine alkaloid and some of its combinations, such as theobromine sodium salicylate and theobromine calcium salicylate, when the drugs are used intravenously? 3. What is the water solubility of theobromine alkaloid? What is the most soluble salt of this drug? 4. What are the signs of abnormal reactions encountered with full dosage of theobromine and its preparation? 5. Are theobromine or its preparation incompatible for intravenous use in combination with methenamine, sodium iodide, sodium salicylate, or with any of these used with it singly? 6. What is the relative efficiency in the liberation of formaldehyde in the urine of 1 Gm. of methenamine given by mouth and the same dose given intravenously?

G. D. M. LAMBDIN, M.D., Electra, Texas

ANSWER—1. Because of its slight solubility, theobromine alkaloid is not used as such; and it certainly could not be given intravenously. For theobromine sodiumsalicylate the dosage on intravenous administration ranges from 0.3 to 1 Gm. given in 10 per cent solution. Symptoms of overdosage are headache, dizziness, restlessness, nausea, vomiting and epileptiform convulsions.

2. Theobromine alkaloid could not be used intravenously, because of its insolubility. Theobromine sodiumsalicylate and theobromine calcium salicylate are probably equivalent on intravenous administration.

3. The solubility of theobromine is very slight, while that of theobromine sodiumsalicylate is as great as 1:1 when freshly prepared. It absorbs carbon dioxide from moist air, which liberates theobromine and hence makes it less soluble. A small amount of sodium salicylate will clear a strong solution.

4. Anorexia, nausea, vomiting, diarrhea, headache, dizziness, somnolence, palpitation, dyspnea, collapse. It may cause generalized erythema.

5. There is no incompatibility in these agents singly or combined.

6. There is no difference in the efficiency of methenamine on oral or intravenous administration, as the degree of liberation of formaldehyde depends on the degree of acidity of the urine. The intravenous use is not to be recommended.

NUMBNESS OF ARMS

To the Editor—I have a woman patient, aged 42, who is apparently normal in every way and robust in build, who is greatly troubled by numbness in both arms coming on during sleep. On awakening, massage and exercise for several minutes are required to restore sensation. This began six years ago, at first occasionally after hard work, now for a year every night. She is less affected if she lies on her back, but if she lies on either side the upper arm is also affected. Recently carrying a basket on either arm at a right angle has brought on the numbness, which is relieved by allowing both arms to hang down by the side. The arms ache after the numbness has passed off. There is no swelling, except of the fingers slightly at times. There is no redness, blueness nor paleness during the attacks. The patient does not have numbness in the lower limbs. Formerly only the hands and forearms were affected but recently it has been extending up to the shoulders. The patient has a sore spot with tenderness over the external condyle of the humerus on the left arm. She has a good grip in both hands. She is awakened every two or three hours by the numbness. If she lies continuously on her back she can sometimes pass the night without an attack. What is the probable diagnosis as to the cause and is there any treatment? Please omit name.

M.D., Missouri.

ANSWER—The occurrence of the numbness in certain postures and under certain conditions suggests the existence of some source of pressure that operates only under these conditions. It is certainly indicated that the presence of cervical ribs as a source of pressure should be eliminated by taking roentgenograms. Failing a positive finding by this means, the only remaining recommendation is that a thorough neurologic examination should be made.

BILATERAL EPIDIDYMITIS

To the Editor—About three weeks ago I noticed that my left testicle was tender. Later in the day it was slightly enlarged and rather painful. By the third day I was unable to be on my feet, as it caused much pain and swelling. Then the right testicle became very tender, slightly enlarged and somewhat painful. Now, after three weeks, I am able to be on my feet, but both testicles are still tender. The left one remains about three times the normal size, the right one slightly under twice the normal size, and I just do not get my "pep" back. The pulse is twelve beats under normal. Several physicians have attended me. I have had calomel purges, local poultices and medicines. I have been charted up at a hospital and nothing wrong was found except a slight enlargement of the prostate, which, it was decided, might be causing the trouble. I have never had venereal disease, am 65 years old, and my urinary function is normal. If you can help me with diagnosis and treatment, I will be thankful. Please omit name and address.

M.D., Colorado.

ANSWER—A diagnosis without examination is difficult. The history suggests a bilateral epididymitis secondary to a prostatitis and seminal vesiculitis. There may be a beginning hyperplastic change of the prostate underlying this. Rest and heat will in all probability clear up the acute phase of this condition. Later investigation as to the underlying cause and its correction should be carried out.

SYMPTOMS AFTER NEPHRECTOMY

To the Editor—I have a patient, a man of 39, who had nephrectomy performed about nine years ago for tuberculosis of the left kidney. Except for painful and frequent micturition, he has no complaints and appears to be in good health. Urinalysis shows a moderate amount of albumin and pus cells. What treatment would you outline for the relief of his symptoms? Would tuberculin injections be of value in this case? Please omit name.

M.D., Ohio.

ANSWER—The patient may have an involvement of the remaining kidney, and this should be studied. If the symptoms are due entirely to bladder lesions, which are frequently associated with tuberculosis of the kidney and continue for a long time after the removal of the diseased organ, the bladder should be treated locally. Instillations into the bladder of 2

per cent phenol (carbolic acid) solution frequently give relief and in all probability have some influence on the healing of the ulcerations. Tuberculin injections may be of some value, but this remedy should be used by one who is familiar with its administration. In the hands of the inexperienced, it may do more harm than good.

INNERVATION OF DENTAL PULP

To the Editor—Perhaps you can straighten me out on this question recently asked me by a dentist: Why is it that an infiltration or conduction local anesthesia will permit grinding and extracting in the bicusps but will not permit touching the pulp, when an intraosseous injection of the same solution will allow the pulp of the bicuspid to be painlessly removed? Does the pulp have a separate innervation from small nerve filaments passing from the alveolus through the cementum and dentin, or what? If published, please omit name.

M D, California.

ANSWER.—So far as is known, the only nerve fibers entering the dental pulp pass through the canals in the apex of the tooth root. No one has ever reported the finding of nerve fibers passing through the cementum on the side of the root into the dentin. From the practical standpoint the question was referred to the department of surgery, which answered as follows:

In either infiltration or block local anesthesia not all of the sensory fibers may be controlled. For example, block anesthesia of the third division of the fifth nerve at the mandibular foramen, sufficient anesthesia may be produced for surgical purposes and yet the filaments supplying the pulp of an individual tooth may not be necessarily anesthetized. The fifth nerve is a large nerve and a block anesthetic may be sufficient for gross surgery. Then, too, the time element is important. The pulp of a tooth may be sensitive shortly after the analgesia has spread to the tissues supplied by the particular branch. If sufficient time is allowed, the analgesia will probably deepen to exclude all pain.

INTRA-UTERINE DEATH OF FETUS

To the Editor—A white woman, aged 34, whose menstrual history is not remarkable, presents the following history of pregnancies and infant and fetal deaths. The blood pressure during pregnancy has varied between 120/80 and 150/90. The urinalysis has always been negative. The first pregnancy resulted in a normal child, who died of diphtheria at the age of 2 years. A second child was born at term. Jaundice developed and it died three days post partum. The third pregnancy resulted in a stillbirth after six or seven months. The fourth terminated with the birth of a normal boy, who is now 7 years old. The fifth resulted in a stillbirth after seven months. During the sixth pregnancy, fetal movements ceased at six and one-half months and the patient was delivered, March 15, 1934, about eight months after conception. I attended the patient only on the occasion of her sixth delivery. The fetus was rather firm, the placenta was small and showed numerous infarcts. One month later the uterus has involuted to normal size and is anterior in position. There are no palpable pelvic masses, no pain or cervical ulcerations. The Wassermann reaction is negative. Can you suggest a cause for the intra uterine fetal deaths and treatment that might enable the patient to give birth to another living child? Please omit name.

M D, Alabama.

ANSWER.—Intra-uterine death is frequently due to thyroid dysfunction. This patient should have one or more tests of the basal metabolism to ascertain the condition of the thyroid. If an abnormality of thyroid function is diagnosed it should be treated. More frequently, a hypothyroidism is discovered and an extract of thyroid should be prescribed. The Wassermann and Kahn reactions of the blood of the patient and her husband should be repeated to rule out latent syphilis, which must be treated if it is discovered.

HEBERDEN'S NODE

To the Editor—A patient with chronic arthritis of the distal phalangeal joints rather suddenly developed a Heberden's node during an acute exacerbation. This remains after several weeks as a slightly movable painless tumor about 5 mm in diameter. It feels like a tense cyst. What is the best treatment? Can it be excised safely?

WALTER J. ROBBINS, M.D., New Britain, Conn

ANSWER.—A gouty diathesis should be excluded in this case. Enucleation and examination for biurate crystals would be indicated in the situation described.

SPINAL CORD INJURY AND IMPOTENCE

To the Editor—Kindly advise me whether it is possible for a man with complete severance of the spinal cord at the fifth dorsal vertebra to have an erection of the penis. I have a patient completely paralyzed from the nipples down following an injury to the back who gets an occasional erection. Kindly omit name.

M D, Pennsylvania.

ANSWER.—Yes, it is possible for the patient to have erections when the lesion is as high as it is in this case.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral (Group A and Group B candidates) San Antonio, Texas, Nov. 13-16 Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written (Group B candidates). The examination will be held in various cities of the United States and Canada, Nov. 3. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: San Antonio, Texas, Nov. 12; Philadelphia, June 10. Sec., Dr. William H. Wilder, 122 S. Michigan Bldg., Chicago

AMERICAN BOARD OF OTOLARYNGOLOGY: San Antonio, Texas, Nov. 16 Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha

ARKANSAS: Basic Science. Little Rock, Nov. 5. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. Regular. Little Rock, Nov. 12 Sec., Dr. A. S. Buchanan, Prescott. Eclectic. Little Rock, Nov. 13. Sec., Dr. L. L. Marshall, 820 W. 14th St., Little Rock.

CALIFORNIA: Sacramento, Oct. 15-18. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento

CONNECTICUT: Basic Science. New Haven, Oct. 13. Prerequisite to license examination. Address, State Board of Healing Arts, 1895 Yale Station, New Haven. Regular. Hartford, Nov. 13-14. Endorsement Hartford, Nov. 27. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homoeopathic. New Haven, Nov. 13 Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

FLORIDA: Tampa, Nov. 12-13. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 9-10. Joint Secretary, State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta

ILLINOIS: Chicago, Oct. 16-18. Superintendent of Registration, Department of Registration and Education, Mr. Eugene R. Schwartz, Springfield

IOWA: Des Moines, Oct. 8-10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines

MAINE: Portland, Nov. 13-14. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton Jr., 192 State St., Portland.

MASSACHUSETTS: Boston, Nov. 13-15. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 144 State House, Boston.

MICHIGAN: Lansing, Oct. 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 16-18. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul.

MISSOURI: Kansas City, Oct. 24. State Health Commissioner, Dr. L. T. McLaughlin, State Capitol Bldg., Jefferson City.

NEBRASKA: Lincoln, Nov. 22-23. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln

NEVADA: Carson City, Nov. 5. Sec., Dr. Edward E. Hamer, Carson City.

NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. James J. McGuire, 28 W. State St., Trenton

NEW MEXICO: Santa Fe, Oct. 8-9. Sec., Dr. P. G. Cornish Jr., 221 W. Central Ave., Albuquerque

OREGON: Basic Science. Portland, Nov. 17. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Georgia June Examination

Mr. R. C. Coleman, joint secretary, State Examining Boards, reports the written examination held by the Georgia State Board of Medical Examiners, June 14-15, 1934. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Eighty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine (1934)	82.8, 83.8, 84.4, 84.6, 84.9, 85, 85.1, 85.6, 85.8, 86.3, 86.4, 86.8, 86.9, 87.1, 87.2, 87.7, 87.8, 87.8, 87.9, 87.9, 88, 88.1, 88.2, 88.3, 88.5, 88.6, 88.6, 88.6, 88.7, 88.9, 88.9, 89.2, 89.3, 89.3, 89.4, 90.7, 91, 97	(1933)	89.5,
University of Georgia School of Medicine (1934)	85.3, 85.9, 86, 86.1, 86.2, 86.4, 86.5, 86.6, 86.8, 87.2, 87.5, 87.5, 87.6, 87.8, 87.8, 87.8, 88, 88, 88.1, 88.1, 88.4, 88.5, 88.6, 88.6, 88.7, 88.9, 89.1, 89.1, 89.3, 89.3, 89.5, 89.5, 90.6, 91.1, 91.5	(1933)	84.9,
University of Nebraska College of Medicine (1933)		(1933)	88.6
University of Texas School of Medicine (1931)		(1931)	91.6

Eight physicians were licensed by reciprocity from June 18 to July 17. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine (1931)		(1931)	Mississippi
University of Louisville School of Medicine (1928)		(1928)	Kentucky
Tulane University of Louisiana School of Medicine (1933)		(1933)	Alabama
University of Minnesota Medical School (1930)		(1930)	Minnesota
Albany Medical College (1898)		(1898)	S. Carolina
Jefferson Medical College of Philadelphia (1928)		(1928)	Vermont
University of Tennessee College of Medicine (1920)		(1920)	Tennessee
Medical College of Virginia (1930)		(1930)	Tennessee

Arizona July Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held in Phoenix, July 5-6, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, 4 of whom passed and 2 failed. Four physicians were licensed by reciprocity. The following schools were represented:

PASSED		Year	Per
School		Grad.	Cent
University of Illinois College of Medicine.....	(1933)		76.1

Book Notices

Chinese Medicine. By William R. Morse, M.D., LL.D., F.A.C.S., Dean of Medical School, Head of Department of Anatomy and Associate in Surgery, West China Union University, College of Medicine and Dentistry, Chengtu, Szechwan Province, West China. No. 11, *Ch'o Medica: A Series of Primers on the History of Medicine*. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$2.50. Pp. 185, with illustrations. New York: Paul B. Hoeber, Inc., 1934.

This volume of the series of primers on the history of medicine under the editorship of E. B. Krumbhaar covers what is probably the longest continuous phase of medical history in human civilization. Chinese medicine in the national cultural sense is still a living and going concern serving [?] as many sick human beings as any other school of medicine even today. This school exists not only in the old civilization of China but also in some other parts of the world where Chinese herb doctors flourish. Devotees of the Chinese cult are not confined to the yellow race or the Flowery Kingdom; thousands of supposedly grateful patients recently followed the bier of a much advertised Chinese doctor in a western city.

The primer of Dr. Morse is from the pen of one familiar with Chinese life, philosophy and civilization, as well as Chinese medicine in both its theory and its practice. He is the head of the department of anatomy and associate in surgery in the Medical College of the West China Union University at Chengtu, Szechwan Province. His primer differs greatly from Wong and Wu Lien-Teh's recently published *History of Chinese Medicine* in that there is no attempt to show the accomplishments of Chinese medicine, no elaborate history of the classic writers and no discussion of the transition into the modern period. It is rather an exposition of the underlying philosophy of Chinese civilization in its definite relations to the basic principles on which Chinese medical theory and practice rest. The point of view is frankly objective and critical without a trace of prejudice or display of the curious and unusual.

The Chinese culture is based on agriculture. Its medicine rests on a mystic cosmogony, with a strong admixture of alchemy. It is entirely lacking in the quickening influences of the critical, open-minded experimental method. It rests on an elaborate, shrewd and cunning logic, but as far as medicine is concerned either the premises are false or the conclusions are wrong. Medicine in China was at its zenith during the Han dynasty (170 A. D.) but the creative urge was smothered by intricate reasoning veiled in mysticism. It has become a tapestry of empiricism in which magic and religion, superstition and spiritism, credulity and ignorance, deception and quackery form a large part. To the Yang and Yin theory of the dualistic concept of nature there is added the basic idea of the five elements, which combine in a mystical array of relations the influences of which are held to determine the functions of the body and all the hygienic and therapeutic measures for the control of health and the causes and cure of disease. To this

there is added a celestial ministry of the ancestral gods, the King of Remedies and the specialists, including Tung Pin, the Aesculapius of Chinese medicine, and Chang Chung Ching, who rates as Hippocrates. Minor gods control the various organs of the body and various diseases from diarrhea to toothache. Worry, poverty and disease are the heritage of China's millions. Fear of the unknown has intermingled their religion, ethics and medicine on the groundwork of their cosmogony.

The author reviews Chinese medicine and pathology but concludes with the statement that some of their conclusions were good guesses but are unsubstantiated by proof. His opinion of Chinese anatomy is not much better. It is controlled by numerical and logical concepts, not by observation. The Chinese "Father of Anatomy," clad in a silken gown, with his three or four inch fingernails, painting illustrations for a treatise of anatomy, does not match well with the tens of years of expert dissection of John Hunter. There is no physiology worthy of the name, and the diagnosis rests on an exaggerated evaluation of the pulse. About 156 volumes have been written by Chinese specialists on the pulse, but few are of more than historical value. Materia medica and therapeutics have their font and origin in Chinese cosmogony. Their contributions include hydrotherapy, psychotherapy, smallpox inoculation, regulation of diet, hot tea, moderation and ephedrine. However, Chinese internal medication is a phantasmagoria, though the "incurable" sometimes recover under their treatment, which proves nothing. The author concludes that there are undoubtedly very valuable medicines in the Chinese armamentarium but that their methods are unscientific, irrational and ineffective.

Needling, or acupuncture, is explained with detailed diagrams. Its purpose is to puncture and penetrate at certain definite points one or more of certain twelve hypothetical, invisible, undetectable channels or *ch'in* which, according to theory, contain the vital Yang and Yin. The needling adjusts the balance between these opposed principles and thus restores health. Moxibustion on the spot of puncture is used to supplement the treatment. If infection results it is due to the disease, not to the treatment!

In an attempt to balance the scales perhaps about all one can say is that in early days a thousand or more years ago and before that time, China's healers did make a contribution to medical science, and, for that age and civilization, their practices were above those of many nations. It cannot be gainsaid, for instance, that China discovered some excellent remedies. At the present time their medical procedures are of merely academic interest to the medical and scientific historian and of perhaps more interest to the philosopher and metaphysician. As far as modern scientific medicine is concerned, speaking broadly, their procedures are of no actual value unless along the line of suggestive and psychologic therapeutics.

A Textbook of Orthopedic Surgery for Nurses. By Philip Lewin, M.D., F.A.C.S., Associate Professor of Orthopedic Surgery, Northwestern University Medical School. Second edition. Cloth. Price, \$3.25. Pp. 389, with 200 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

This treatise on orthopedic surgery fulfils the purpose expressed in the preface, "to outline a series of principles which will make the nurse competent to care for the orthopedic patient, to assist the orthopedic surgeon in all branches of his work." The subject of orthopedic nursing has been inadequately dealt with in most of the nursing schools of the past. This has been due in part to the fact that books on orthopedic surgery have for the most part been too advanced to be suitable for the student nurse. Dr. Lewin has written in a simple, straightforward style, and the arrangement of the book, beginning with a brief statement on the general orthopedic considerations, embryology, anatomy and physiology of the bones and joints and their related structures first creates a background for a better understanding of the chapters that deal with the clinical problems. At all times this excellent book keeps the nursing point of view foremost. The author emphasizes the fact, which orthopedic surgeons have come to recognize, that the final result in the treatment of the patient depends as much on good nursing care as it does on the doctor himself. In the average general hospital the orthopedic patient is dreaded by the nurses on the floors, particularly if that patient requires care in plaster casts. This dread is based almost entirely on the fact that the nurses

per cent phenol (carbolic acid) solution frequently give relief and in all probability have some influence on the healing of the ulcerations. Tuberculin injections may be of some value, but this remedy should be used by one who is familiar with its administration. In the hands of the inexperienced, it may do more harm than good.

INNERVATION OF DENTAL PULP

To the Editor:—Perhaps you can straighten me out on this question recently asked me by a dentist: Why is it that an infiltration or conduction local anesthesia will permit grinding and extracting in the bicuspid but will not permit touching the pulp, when an intra-osseous injection of the same solution will allow the pulp of the bicuspid to be painlessly removed? Does the pulp have a separate innervation from small nerve filaments passing from the alveolus through the cementum and dentin, or what? If published, please omit name.

M.D., California.

ANSWER.—So far as is known, the only nerve fibers entering the dental pulp pass through the canals in the apex of the tooth root. No one has ever reported the finding of nerve fibers passing through the cementum on the side of the root into the dentin. From the practical standpoint the question was referred to the department of surgery, which answered as follows:

In either infiltration or block local anesthesia not all of the sensory fibers may be controlled. For example, block anesthesia of the third division of the fifth nerve at the mandibular foramen, sufficient anesthesia may be produced for surgical purposes and yet the filaments supplying the pulp of an individual tooth may not be necessarily anesthetized. The fifth nerve is a large nerve and a block anesthetic may be sufficient for gross surgery. Then, too, the time element is important. The pulp of a tooth may be sensitive shortly after the analgesia has spread to the tissues supplied by the particular branch. If sufficient time is allowed, the analgesia will probably deepen to exclude all pain.

INTRA-UTERINE DEATH OF FETUS

To the Editor:—A white woman, aged 34, whose menstrual history is not remarkable, presents the following history of pregnancies and infant and fetal deaths: The blood pressure during pregnancy has varied between 120/80 and 150/90. The urinalysis has always been negative. The first pregnancy resulted in a normal child, who died of diphtheria at the age of 2 years. A second child was born at term. Jaundice developed and it died three days post partum. The third pregnancy resulted in a stillbirth after six or seven months. The fourth terminated with the birth of a normal boy, who is now 7 years old. The fifth resulted in a stillbirth after seven months. During the sixth pregnancy, fetal movements ceased at six and one-half months and the patient was delivered, March 15, 1934, about eight months after conception. I attended the patient only on the occasion of her sixth delivery. The fetus was rather firm; the placenta was small and showed numerous infarcts. One month later the uterus has involuted to normal size and is anterior in position. There are no palpable pelvic masses, no pain or cervical ulcerations. The Wassermann reaction is negative. Can you suggest a cause for the intra-uterine fetal deaths and treatment that might enable the patient to give birth to another living child? Please omit name.

M.D., Alabama.

ANSWER.—Intra-uterine death is frequently due to thyroid dysfunction. This patient should have one or more tests of the basal metabolism to ascertain the condition of the thyroid. If an abnormality of thyroid function is diagnosed it should be treated. More frequently, a hypothyroidism is discovered and an extract of thyroid should be prescribed. The Wassermann and Kahn reactions of the blood of the patient and her husband should be repeated to rule out latent syphilis, which must be treated if it is discovered.

HEBERDEN'S NODE

To the Editor:—A patient with chronic arthritis of the distal phalangeal joints rather suddenly developed a Heberden's node during an acute exacerbation. This remains after several weeks as a slightly movable painless tumor about 5 mm. in diameter. It feels like a tense cyst. What is the best treatment? Can it be excised safely?

WALTER J. ROBBINS, M.D., New Britain, Conn.

ANSWER.—A gouty diathesis should be excluded in this case. Enucleation and examination for biurate crystals would be indicated in the situation described.

SPINAL CORD INJURY AND IMPOTENCE

To the Editor:—Kindly advise me whether it is possible for a man with complete severance of the spinal cord at the fifth dorsal vertebra to have an erection of the penis. I have a patient completely paralyzed from the nipples down following an injury to the back who gets an occasional erection. Kindly omit name.

M.D., Pennsylvania.

ANSWER.—Yes, it is possible for the patient to have erections when the lesion is as high as it is in this case.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Oral (Group A and Group B candidates). San Antonio, Texas, Nov. 13-16. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written (Group B candidates). The examination will be held in various cities of the United States and Canada, Nov. 3. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: San Antonio, Texas, Nov. 12; Philadelphia, June 10. Sec., Dr. William H. Wilder, 122 S. Michigan Blvd., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: San Antonio, Texas, Nov. 16. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

ARKANSAS: Basic Science. Little Rock, Nov. 5. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. Regular. Little Rock, Nov. 12. Sec., Dr. A. S. Buchanan, Prescott. Eclectic. Little Rock, Nov. 13. Sec., Dr. L. L. Marshall, 820 W. 14th St., Little Rock.

CALIFORNIA: Sacramento, Oct. 15-18. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: Basic Science. New Haven, Oct. 13. Prerequisite to license examination. Address, State Board of Healing Arts, 1895 Yale Station, New Haven. Regular. Hartford, Nov. 13-14. Endorsement. Hartford, Nov. 27. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Homeopathic. New Haven, Nov. 13. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

FLORIDA: Tampa, Nov. 12-13. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 9-10. Joint Secretary, State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

ILLINOIS: Chicago, Oct. 16-18. Superintendent of Registration, Department of Registration and Education, Mr. Eugene R. Schwartz, Springfield.

IOWA: Des Moines, Oct. 8-10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MAINE: Portland, Nov. 13-14. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton Jr., 192 State St., Portland.

MASSACHUSETTS: Boston, Nov. 13-15. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 144 State House, Boston.

MICHIGAN: Lansing, Oct. 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-34 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, Oct. 16-18. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul.

MISSOURI: Kansas City, Oct. 24. State Health Commissioner, Dr. E. T. McLaughlin, State Capitol Bldg., Jefferson City.

NEBRASKA: Lincoln, Nov. 22-23. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Carson City, Nov. 5. Sec., Dr. Edward E. Hamer, Carson City.

NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 8-9. Sec., Dr. P. G. Cornish Jr., 221 W. Central Ave., Albuquerque.

OREGON: Basic Science. Portland, Nov. 17. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. A. Earle Booser, 505 Saluda Ave., Columbia.

Georgia June Examination

Mr. R. C. Coleman, joint secretary, State Examining Boards, reports the written examination held by the Georgia State Board of Medical Examiners, June 14-15, 1934. The examination covered 10 subjects and included 100 questions. An average of 80 per cent was required to pass. Eighty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....(1933)			89.5.
(1934) 82.8, 83.8, 84.4, 84.6, 84.9, 85, 85.1, 85.6, 85.8, 86.3, 86.4, 86.8, 86.9, 87.1, 87.2, 87.7, 87.8, 87.8, 87.8, 87.9, 87.9, 88, 88.1, 88.2, 88.3, 88.5, 88.6, 88.6, 88.6, 88.7, 88.7, 88.9, 88.9, 89.2, 89.3, 89.3, 89.4, 90.7, 91, 97			
University of Georgia School of Medicine.....(1934)			84.9.
85.3, 85.9, 86, 86.1, 86.2, 86.4, 86.5, 86.6, 86.8, 87.2, 87.5, 87.5, 87.6, 87.8, 87.8, 87.8, 88, 88, 88.1, 88.1, 88.1, 88.4, 88.5, 88.6, 88.7, 88.9, 89.1, 89.1, 89.3, 89.3, 89.5, 89.5, 90.6, 91.1, 91.5			
University of Nebraska College of Medicine.....(1933)			88.6
University of Texas School of Medicine.....(1931)			91.6

Eight physicians were licensed by reciprocity from June 18 to July 17. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Emory University School of Medicine.....(1931)			Mississippi
University of Louisville School of Medicine.....(1928)			Kentucky
Tulane University of Louisiana.....(1933)			Alabama
University of Minnesota Medical School.....(1930)			Minnesota
Albany Medical College.....(1898)			S. Carolina
Jefferson Medical College of Philadelphia.....(1928)			Vermont
University of Tennessee College of Medicine.....(1920)			Tennessee
Medical College of Virginia.....(1930)			Tennessee

Arizona July Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held in Phoenix, July 5-6, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, 4 of whom passed and 2 failed. Four physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year	
		Grad.	Per Cent
University of Illinois College of Medicine.....	(1933)		76.1
University of Kansas School of Medicine.....	(1933)		80.7
University of Michigan Medical School.....	(1932)		83.1
Baylor University College of Medicine.....	(1933)		76.4
School	FAILED	Year	
		Grad.	Per Cent
College of Medical Evangelists	(1933)		74.7
George Washington University School of Medicine.....	(1933)		72.3
School	LICENSED BY RECIPROCITY	Year	
		Grad.	Reciprocity with
University of Illinois College of Medicine.....	(1929)		California
University of Michigan Medical School.....	(1927)		Minnesota
Western Reserve University School of Medicine.....	(1923)		Ohio
Marquette University School of Medicine.....	(1926)		Wisconsin

Book Notices

Chinese Medicine. By William R. Morse, M.D., LL.D., F.A.C.S., Dean of Medical School, Head of Department of Anatomy and Associate in Surgery, West China Union University, College of Medicine and Dentistry, Chengtu, Szechwan Province, West China. No. 11, *Chlo Medica: A Series of Primers on the History of Medicine*. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$2.50. Pp. 185, with illustrations. New York: Paul B. Hoeber, Inc., 1934.

This volume of the series of primers on the history of medicine under the editorship of E. B. Krumbhaar covers what is probably the longest continuous phase of medical history in human civilization. Chinese medicine in the national cultural sense is still a living and going concern serving [?] as many sick human beings as any other school of medicine even today. This school exists not only in the old civilization of China but also in some other parts of the world where Chinese herb doctors flourish. Devotees of the Chinese cult are not confined to the yellow race or the Flowery Kingdom; thousands of supposedly grateful patients recently followed the bier of a much advertised Chinese doctor in a western city.

The primer of Dr. Morse is from the pen of one familiar with Chinese life, philosophy and civilization, as well as Chinese medicine in both its theory and its practice. He is the head of the department of anatomy and associate in surgery in the Medical College of the West China Union University at Chengtu, Szechwan Province. His primer differs greatly from Wong and Wu Lien-Teh's recently published *History of Chinese Medicine* in that there is no attempt to show the accomplishments of Chinese medicine, no elaborate history of the classic writers and no discussion of the transition into the modern period. It is rather an exposition of the underlying philosophy of Chinese civilization in its definite relations to the basic principles on which Chinese medical theory and practice rest. The point of view is frankly objective and critical without a trace of prejudice or display of the curious and unusual.

The Chinese culture is based on agriculture. Its medicine rests on a mystic cosmogony, with a strong admixture of alchemy. It is entirely lacking in the quickening influences of the critical, open-minded experimental method. It rests on an elaborate, shrewd and cunning logic, but as far as medicine is concerned either the premises are false or the conclusions are wrong. Medicine in China was at its zenith during the Han dynasty (170 A. D.) but the creative urge was smothered by intricate reasoning veiled in mysticism. It has become a tapestry of empiricism in which magic and religion, superstition and spiritism, credulity and ignorance, deception and quackery form a large part. To the Yang and Yin theory of the dualistic concept of nature there is added the basic idea of the five elements, which combine in a mystical array of relations the influences of which are held to determine the functions of the body and all the hygienic and therapeutic measures for the control of health and the causes and cure of disease. To this

there is added a celestial ministry of the ancestral gods, the King of Remedies and the specialists, including Tung Pin, the Aesculapius of Chinese medicine, and Chang Chung Ching, who rates as Hippocrates. Minor gods control the various organs of the body and various diseases from diarrhea to toothache. Worry, poverty and disease are the heritage of China's millions. Fear of the unknown has intermingled their religion, ethics and medicine on the groundwork of their cosmogony.

The author reviews Chinese medicine and pathology but concludes with the statement that some of their conclusions were good guesses but are unsubstantiated by proof. His opinion of Chinese anatomy is not much better. It is controlled by numerical and logical concepts, not by observation. The Chinese "Father of Anatomy," clad in a silken gown, with his three or four inch fingernails, painting illustrations for a treatise of anatomy, does not match well with the tens of years of expert dissection of John Hunter. There is no physiology worthy of the name, and the diagnosis rests on an exaggerated evaluation of the pulse. About 156 volumes have been written by Chinese specialists on the pulse, but few are of more than historical value. *Materia medica* and therapeutics have their font and origin in Chinese cosmogony. Their contributions include hydrotherapy, psychotherapy, smallpox inoculation, regulation of diet, hot tea, moderation and ephedrine. However, Chinese internal medication is a phantasmagoria, though the "incurable" sometimes recover under their treatment, which proves nothing. The author concludes that there are undoubtedly very valuable medicines in the Chinese armamentarium but that their methods are unscientific, irrational and ineffective.

Needling, or acupuncture, is explained with detailed diagrams. Its purpose is to puncture and penetrate at certain definite points one or more of certain twelve hypothetic, invisible, undetectable channels or *ch'in* which, according to theory, contain the vital Yang and Yin. The needling adjusts the balance between these opposed principles and thus restores health. Moxibustion on the spot of puncture is used to supplement the treatment. If infection results it is due to the disease, not to the treatment!

In an attempt to balance the scales perhaps about all one can say is that in early days a thousand or more years ago and before that time, China's healers did make a contribution to medical science, and, for that age and civilization, their practices were above those of many nations. It cannot be gainsaid, for instance, that China discovered some excellent remedies. At the present time their medical procedures are of merely academic interest to the medical and scientific historian and of perhaps more interest to the philosopher and metaphysician. As far as modern scientific medicine is concerned, speaking broadly, their procedures are of no actual value unless along the line of suggestive and psychologic therapeutics.

A Textbook of Orthopedic Surgery for Nurses. By Philip Lewin, M.D., F.A.C.S., Associate Professor of Orthopedic Surgery, Northwestern University Medical School. Second edition. Cloth. Price, \$3.25. Pp. 389, with 200 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

This treatise on orthopedic surgery fulfils the purpose expressed in the preface, "to outline a series of principles which will make the nurse competent to care for the orthopedic patient, to assist the orthopedic surgeon in all branches of his work." The subject of orthopedic nursing has been inadequately dealt with in most of the nursing schools of the past. This has been due in part to the fact that books on orthopedic surgery have for the most part been too advanced to be suitable for the student nurse. Dr. Lewin has written in a simple, straightforward style, and the arrangement of the book, beginning with a brief statement on the general orthopedic considerations, embryology, anatomy and physiology of the bones and joints and their related structures first creates a background for a better understanding of the chapters that deal with the clinical problems. At all times this excellent book keeps the nursing point of view foremost. The author emphasizes the fact, which orthopedic surgeons have come to recognize, that the final result in the treatment of the patient depends as much on good nursing care as it does on the doctor himself. In the average general hospital the orthopedic patient is dreaded by the nurses on the floors, particularly if that patient requires care in plaster casts. This dread is based almost entirely on the fact that the nurses

feel at a loss to know just what to do in making the patient comfortable and in the prevention of bed sores. The book is well illustrated and can be recommended not only for student nurses but also for the graduate nurse who is assigned to the care of orthopedic cases, the visiting nurse, and the medical student.

Annual Review of Biochemistry. Edited by James Murray Luck. Volume III. Cloth. Price, \$5. Pp. 558. Stanford University, California: Stanford University Press, 1934.

The third volume of this valuable series is as welcome and excellent as the previous Annual Reviews. The advisory committee has adopted the wise policy of attempting to obtain only true reviews of the most important papers with the most direct bearing on the subject rather than to prepare elaborate and noncritical compendiums. As a result, certain special and important papers may not be included in current issues of the Review, but it is to be expected that such papers may be included in special reviews at a later date. The present volume follows the same general plan as in previous issues with the exception that several timely special reviews have been included and several new contributors have been added or substituted. The four new reviews, that is, the chemistry of the sterols, bile acids and other natural fats and oils by O. Rosenheim and H. King, another on biochemical and nutritional studies in the field of dentistry by Martha Koehne and R. W. Bunting, a third on the biochemistry of malignant tissue by E. Boyland and a fourth on the metabolism of carbohydrates and organic acids in plants by W. Ruhland and J. Wolf, are especially welcome at this time. Among the new contributors are A. Bertho, on biologic oxidations and reductions; W. Pauli, on the chemistry of the amino acids and proteins; K. Kotake, on the metabolism of proteins and amino acids; S. Brody, on nutrition, and H. Lundegardh, on mineral nutrition of plants. It is particularly gratifying to see that the certain special chapters are repeated, although some of them may have been omitted in the second volume. Among these are R. O. Gortner's treatment of water in its biochemical relationships, H. D. Kay's review on phosphorus metabolism, L. Ruzicka's summary on terpenes, saponins and closely related compounds, M. Stephenson's review on the chemistry of bacteria, and J. L. Bollman and F. C. Mann's statement on the liver and bile. No worker in biochemistry, no matter how specialized his field may be, can afford to be without this series of reviews.

X-Ray and Radium Injuries: Prevention and Treatment. By Hector A. Colwell, M.B., Ph.D., M.R.C.P., and Sidney Russ, C.B.E., D.Sc., F.Inst.P. Cloth. Price, \$4.75. Pp. 212, with 2 illustrations. New York & London: Oxford University Press, 1934.

In 1915 Dr. Colwell, pathologist and radiologist, and Professor Russ, physicist, wrote a timely monograph entitled "X-Ray, Radium and the Living Cell." They have now written a much needed monograph, essentially a compilation, which gives in a concise manner all obtainable knowledge, both clinical and experimental, relative to injuries of all kinds caused by x-rays, radium and radioactive substances. The little book is divided into fourteen chapters and an appendix in which are discussed general consideration of protection; injuries to the skin, respiratory tract, circulatory system, alimentary tract, generative system, urinary tract, nervous system, eye, ear, bone, cartilage, muscle, connective tissue, suprarenals, thyroid, thymus, mammary gland and subdivisions of all these parts; radiation sickness; changes produced by the prolonged action of gamma radiation; poisoning by radioactive substances; x-ray and radium quackery; recommendations of the British X-Ray and Radium Protective Committee, and methods of dosage. It is thus seen that the work is quite comprehensive. The authors review the literature in addition to giving their own experience and they clearly differentiate at all times between facts, theories, beliefs and impressions. They have collected a large amount of data concerning early and late, mild, severe, serious and fatal injuries to various parts of the body in man and have added all the important knowledge gained by animal experimentation, of which there is considerable. The experimental work on cancer, early and late injuries to the viscera, heredity and toleration are especially interesting and important. Because of authenticity, comprehensiveness and conservatism, there is little to criticize. The clinical and histologic discussions of many

injuries are not elaborate, but those who desire dissertations are referred to reliable articles and books that deal with limited subjects in great detail. A reasonable number of well selected photomicrographs and clinical illustrations would be a valuable addition, although they would make the book larger and more expensive; furthermore, they are contained in the works to which the readers are referred. The index, while answering essential requirements, might be more detailed. For instance, "cataract" is not in the index but it is, of course, described in the section dealing with eye injuries. The literary style used permits rapid assimilation by any physician; therefore the book is of value to general physicians, specialists, scientists and research workers.

Four Leaf Clovers. By Frederick E. Keller, M.D. Cloth. Price, \$1.75. Pp. 148. Philadelphia: Dorrance & Company, Inc., 1934.

Only a few of the poems by Dr. Keller are of particular medical interest; for the most part they deal with the topics that have concerned poets since the beginning of time. The one entitled "Nurse" will have a special appeal for the medical reader:

—
Along some quiet corridor she goes,
With quickened step, to pause beside a bed
To take the pulse and touch the fevered head
Of some one in distress; soothe the woes
Of woman in travail; her instinct flows
In sympathetic words; another led
From fear to confidence; a baby fed
Or given tender care as mother knows.
Among the many forms of humankind
A barrier 'tween life and death she stands.
Now sad, now happy as the time demands;
Be this a token of her helpful kind—
She lives to serve the sick, a deed divine,
Far, far beyond this earth her glories shine.

Vitality. By Boris Sokoloff, M.D., ScD. Cloth. Price, \$2. Pp. 181. New York: E. P. Dutton & Company, Inc., 1934.

The purpose of this book is to popularize recent advances in knowledge of the problems of vitality. The first part deals with vitality of man and of lower animals and with "the gland of life"—the cortex of the suprarenal, the hormone of which is "the hormone of vitality." The second part describes the source of vitality, more particularly lactic acid (acid-base equilibrium, the fuel of the brain, lactic acid as a general antiseptic, the conservatism of lactic acid). The third part is headed "the crisis of vitality—cancer." Here is a chapter on Napoleon's case and a discussion of the revolt of cells and of vitality and cancer. The book has points of interest. Vital phenomena are discussed and explained in apparently simple and convincing language. There can be no question about the confidence of the author in his explanations and reasoning. In most cases, however, the generalizations are more definitive than warranted by existing knowledge.

Les ultravirus: Pathogènes et saprophytes. Techniques d'étude, caractères physiques et biologiques, maladies à ultravirus—Clinique, anatomo-pathologie, épidémiologie, immunité. Par le Dr. Paul Hauduroy, préparateur à la Faculté de médecine de Paris. Paper. Price, 60 francs. Pp. 462. Paris: Masson & Cie, 1934.

The new edition of M. Hauduroy's book on ultraviruses should be welcomed by all those who are interested in this rapidly expanding field of microbiology or wish to acquaint themselves with it. Although the author makes no attempt at completeness, he has succeeded in bringing together most of the recent and important contributions relating to these organisms. The volume is divided into three main divisions. The first treats critically and instructively various technical procedures, such as the preparation and use of porcelain and diatomaceous earth filters and celloidin membranes. There are discussions of cataphoresis and adsorption phenomena and their usefulness and limitations in the manipulation of viruses. Brief chapters are also devoted to tissue culture and staining methods. The second and major part of the book deals with the specific virus diseases of plants, bacteria, insects, birds and mammals. The discussions of the filtrable forms of bacteria have been, for the most part, omitted from this edition. The material concerning each virus is treated under various subheads, and good bibliographies are appended to most of the chapters. Whereas the former edition contained more than 150 references, the present

one contains more than 1,500. Particular emphasis is laid on the physical and physiologic characteristics of the pathogenic viruses. The last portion of the work deals in a more general way with virus physiology and the epidemiology and immunity of virus diseases. The final chapters contain discussions, admittedly highly speculative but none the less interesting, regarding the nature and probable origin of pathogenic and saprophytic viruses. The book contains an index but no illustrations.

Outlines of Nursing History. By Minnie Goodnow, R.N. Fifth edition. Cloth. Price, \$3. Pp. 517, with 162 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

This outline is now in its fifth edition. It is much used as a teaching textbook by many nurses' training schools. The present edition is fully revised and brought up to date. The book gives the history of nursing throughout the world. It is supplemented by a series of appendixes relative to registration, nursing organizations, nursing periodicals and much additional material of practical importance to the nurse in her work.

Recent Advances in Pathology. By Geoffrey Hadfield, M.D., F.R.C.P., Professor of Pathology in the University of Bristol, and Lawrence P. Garrod, M.A., M.D., B.Ch., Bacteriologist and Lecturer in Bacteriology, St. Bartholomew's Hospital. Second edition. Cloth. Price, \$4. Pp. 457, with 69 illustrations. Philadelphia: P. Blunkson's Son & Company, Inc., 1934.

This book appeared first two years ago. It is now revised and expanded to include recent advances in knowledge in various fields of pathology. Silicosis, cancer of the lung, monocytic leukemia, the suprarenal in Addison's disease, the pituitary, and the structural changes in deficiency diseases are cited as examples of topics that have received special attention in this edition. There are seventeen chapters in all. The book contains helpful summaries of the current advances in pathology.

Life in the Making. By Alan Frank Guttmacher, Associate in Obstetrics, Johns Hopkins University. With the assistance of Ellery Rand. Cloth. Price, \$2.75. Pp. 297, with 8 illustrations. New York: Viking Press, 1933.

The author of this volume has a special ability in making clear to any fairly intelligent reader the biologic processes associated with reproduction both in man and in animals. The publisher has done well in printing a book that is easily readable and artistic. The book is divided into six parts covering the basic biologic factors, sex rhythms, disturbances of the male and female development, determination of sex, sterility and fertility, and multiple births. The volume is enlivened with numerous quotations from literature, with epigrams and with case reports. It should be read with great interest not only by the public but also by physicians, who are frequently asked questions which this book answers.

Collens System of Diet Writing Including: Diet Calculator, Obesity Chart, 100 Menu Prescription Forms. By William S. Collens, B.S., M.D., Chief Diabetic Clinic, Israel Zion Hospital, Brooklyn, N. Y. Fabrikoid. Price, \$5.00. Loose-leaf. New York: Form Publishing Company, [n. d.]

This book includes a diet calculator, an obesity chart and 100 menu prescription forms. The diet calculator and the obesity chart provide considerable amounts of data on circulating wheels, so that it is simple for the physician to make up diets containing given amounts of protein, fat and carbohydrate to meet the necessities of cardiorenal disease, neuroses or epilepsy. The obesity diets are calculated to provide menus for the various meals of the day containing definite amounts of protein, fats and carbohydrates and also to meet minimum caloric requirements. The volume should be most useful to general practitioners who feel the need of preparing special diet lists for individual patients in their office practice.

The Doctor and Citizenship. By Thurman D. Kitchin, M.D., President, Wake Forest College. Cloth. Price, \$1.50. Pp. 89. Boston: Christopher Publishing House, 1934.

Here is a reprint of essays by the president of Wake Forest College. Most of these have appeared in *Southern Medicine and Surgery*. The essays deal with such topics as the citizenship of the physician, education, lay control of medicine, cancer, and the qualities of a doctor. They show breadth of culture and a thorough familiarity with the modern medical point of view.

Erblehre und Rassenhygiene im völkischen Staat. Herausgegeben in Gemeinschaft mit namhaften Fachgelehrten von Professor Dr. Ernst Rüdin, Direktor des Kaiser-Wilhelm-Instituts für Genealogie und Demographie der Deutschen Forschungsanstalt für Psychiatrie in München. Paper. Price, 14 marks. Pp. 385, with 64 illustrations. Munich: J. F. Lehmanns Verlag, 1934.

This book contains twenty-two articles by nineteen authors on different phases of genetics, eugenics, and race and sterilization problems. The opening article, by the Bavarian minister of the interior, is highly political. The succeeding chapters on the hereditary basis for race hygiene by a botanist, and race origins by an anthropologist, are good but demonstrate the deplorable tendency of the whole book to adapt scientific facts to promulgated laws. It is unfortunate that so many well trained scientists find it necessary to attempt to reconcile important and valuable facts to an abortive political project.

A Life Against Death. By Kenelm Winslow. Boards. Price, \$3. Pp. 292. Seattle, Washington: Lowman & Hanford Company, 1933.

This autobiography records the life of Dr. Winslow from birth and boyhood in Boston and in New England through a period spent in Florida. He then discusses his medical training in the Massachusetts General Hospital and his early days as a student and teacher and as an intern. The book then goes on to describe his early practice on the Cape, removal to the West, a period of special study in the Mayo Clinic, and his adventures in the World War. The volume is distinctly personal and offers some interesting anecdotes of medical life.

American Pocket Medical Dictionary: Containing the Pronunciation and Definition of All the Principal Terms Used in Medicine, Surgery, Dentistry, Veterinary Medicine, Nursing, and Kindred Sciences With Over 60 Extensive Tables. Edited by W. A. Newman Dorland, A.M., M.D. Fifteenth edition. Fabrikoid. Price, \$2; indexed, \$2.50. Pp. 920. Philadelphia & London: W. B. Saunders Company, 1934.

Now in its fifteenth edition, this is one of the most popular pocket medical dictionaries available. It has been entirely reset from new type and increased in size by nearly 100 pages. Over 5,000 new terms have been added and many definitions revised to meet new uses. Significant of the growth of the medical vocabulary is the fact that this volume has gradually increased in size from a little over 500 pages to over 900 pages.

Human Sex Anatomy. By Robert Latou Dickinson, M.D., F.A.C.S. A Topographical Hand Atlas. Medical Aspects of Human Fertility Series Issued by the National Committee on Maternal Health, Inc. Cloth. Price, \$10. Pp. 145, with 175 illustrations. Baltimore: Williams & Wilkins Company, 1933.

In this atlas the author makes available a large number of black and white drawings relative to the development of the sex organs of man and woman and of the application of these organs to purposes of reproduction. The data are not generally available in any other work, so that its development by Dr. Dickinson constitutes a scientific service.

Medicolegal

Malpractice: Failure to Administer Antitetanic Serum.

—On August 20 Mrs. Thompson stepped on a stick of wood, which turned up and inflicted a wound on the top of her foot. Home remedies were applied and in a few days the inflammation that developed after the accident seemed to have subsided. Ten days later, however, on August 30, her jaws became stiff, she had a pain in her face and neck and she was unable to swallow. She consulted the defendant-physician and told him of her symptoms and gave him a history of the injury to her foot. After examining the foot, the defendant prescribed no treatment. He negated the fear expressed by the husband that the patient was suffering from tetanus and attributed her present condition to a cold. He advised her that if she became any worse by morning to go to a hospital. About eleven that night the patient had a convulsion. Early the following morning the defendant was called and in accordance with his instructions the patient was taken to a hospital, where she was attended by another physician. This physician made a diagnosis of tetanus, opened and treated the wound, and gave antitetanic serum. The patient grew steadily worse and died the following

day. The husband, as administrator of his wife's estate, sued the defendant, alleging that the death of his wife was caused by the defendant's negligence. At the close of the plaintiff's evidence, the trial court directed a verdict in the defendant's favor and the plaintiff appealed to the Supreme Court of Iowa.

The sole question for determination, said the Supreme Court, is whether or not the evidence presented facts from which the jury should have been allowed to determine whether or not the death of the patient was caused by the defendant's negligence. In malpractice cases it is not sufficient for the plaintiff to show that the defendant did or neglected to do a particular act and that following this commission or omission unfavorable conditions or happenings occurred. The plaintiff must establish a causal connection between the negligence and the unfavorable condition or happening that followed. To show this causal connection, the plaintiff called four expert witnesses. All of these physicians agreed that the proper treatment for an injury from which tetanus might be expected to result is to open and clean the wound and to administer a prophylactic dose of antitetanic serum. None testified, however, that any treatment that the defendant might have administered on the afternoon of August 30, the day the defendant was first called on the case, would have prevented the patient's death, which occurred two days later. One witness stated that even had the defendant-physician given antitetanic serum when he was first called, the fatal outcome of the case would probably not have been averted. To say that the patient's death was caused by anything done or omitted by the defendant, in the opinion of these witnesses, would be pure conjecture and speculation.

The plaintiff placed considerable stress on the testimony of one of the experts that the death rate in cases of tetanus in which the wound is properly taken care of and antitetanic serum given, is about one in four. The mere suggestion, said the court, that a certain percentage of these cases show a recovery can be of no value to the plaintiff, without further evidence tending to place this case in the number of those in which recovery takes place. This witness further testified, however, that by prophylactic treatment he meant treatment administered immediately after the wound was inflicted, that the resistance of a particular individual and the virulence of the germs would make a difference in the results, that the only hope of a cure depends on early treatment, and that the outcome in any case is speculative and conjectural.

The testimony of the expert witnesses, said the court, failed to show any probability that the death of the patient would not have resulted from tetanus regardless of any negligence or malpractice on the part of the defendant. It unmistakably established the fact that any attempt to attribute the death to any act or omission to act on the part of the defendant, rather than to the disease, would be pure speculation and conjecture. If, concluded the court, the attempt to fix the cause of the death of the patient would be speculation and conjecture on the part of experts themselves, it must be clear beyond all doubt that the question should not be submitted to a jury.

The judgment of the lower court was accordingly affirmed.—*Thompson v. Anderson (Iowa)*, 252 N. W. 117.

Workmen's Compensation Acts: Death Following Vaccination an Accidental Injury.—William Tucker was employed by the Spicer Manufacturing Company, Feb. 26, 1930. Eight days later he was ordered by his foreman to report to the first-aid plant hospital located on the premises. He did so and was there vaccinated by the company physician. Fifteen or twenty minutes thereafter he resumed his work. His left arm gradually became so inflamed, swollen and painful that at the end of five days he was unable to continue his employment. He died, March 29, 1930. It was agreed that the death resulted directly from the vaccination. His widow filed claim against the company with the industrial commission and from an order disallowing the claim she appealed to the court of common pleas of Lucas county. There the trial resulted in a verdict for the widow and eventually the case came before the Supreme Court of Ohio.

The question presented for consideration, said the Supreme Court, is whether, under the combination of circumstances in the case, the death of the employee resulted from an accidental physical injury arising out of or in the course of employment.

That the employee received a physical injury seems clear, said the court. The process of vaccination necessitated a scarifying and laceration of the skin and flesh. This constituted a physical injury to the tissues of the arm. The company, in contending that the vaccination was not an accident, argued that the employee's death resulted simply because he was one of those individuals whose system could not withstand the introduction of vaccine. The widow, on the other hand, insisted that the death may have been caused either in this wise or by other infection entering the vaccination wound. Irrespective of which thing happened, said the court, it was manifestly unforeseen, unusual and unexpected, and therefore accidental. The court quoted with approval from the case of *Texas Employers' Ins. Ass'n v. Mitchell* (Texas), 27 S. W. (2d) 600, as follows:

The bodily injury sustained by Mrs. Mitchell was not due, as involved in the finding of the jury, to rheumatism or any other independent disease, but was directly attributable to the infection following the vaccination of her left arm, as must be presumed, taking the evidence most favorable to appellee. The every [very] act of vaccination itself cannot be said to have been an "accident" in the ordinary sense of the word, as it was foreseen, expected, and intended. Mrs. Mitchell went to the doctor's office for that very specific purpose. But the infection and its immediate entry into the system through the vaccination wound was the intervention of an unlooked for circumstance sufficiently constituting the element of accident. There was no intention to have the wound become infected. The vaccination wound and the infection following the vaccination combined to immediately cause and bring about the bodily injury. Therefore such injury would appear, and sufficiently so, to be an injury of accidental nature effected through accidental means.

The court was of the opinion that the employee's injury arose out of or in the course of his employment. It was agreed that the employee would have been discharged if he had not been vaccinated. In other words, it was impossible for him to continue his employment without complying with the company's order. The peremptory nature of the foreman's instruction, observed the court, was shown by the fact that the moment the employee received his order he left his work and went to the plant hospital. Within fifteen or twenty minutes the process of vaccination was completed and he returned to his work. This absence from work resulted in no deduction from his pay. Under this combination of circumstances, concluded the court, it could not be said that the injury did not arise out of and in the course of the employment. The judgment in favor of the widow was accordingly affirmed.—*Spicer Mfg. Co. v. Tucker (Ohio)*, 188 N. E. 870.

COMING MEETINGS

- Academy of Physical Medicine, New York, Oct. 30-31. Dr. Arthur H. Ring, 163 Hillside Avenue, Arlington, Mass., Secretary.
- American College of Surgeons, Boston, Oct. 15-19. Dr. Franklin H. Martin, 40 East Erie Street, Chicago, Director-General.
- American Society of Tropical Medicine, San Antonio, Texas, November 14-16. Dr. Henry E. Melency, Vanderbilt University School of Medicine, Nashville, Tenn., Secretary.
- Associated Anesthetists of the United States and Canada, Boston, Oct. 15-19. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary.
- Association of Military Surgeons of the United States, Carlisle Barracks, Pa., Oct. 8-10. Dr. J. R. Kean, Army Medical Museum, Washington, D. C., Secretary.
- Central Association of Obstetricians and Gynecologists, New Orleans, Nov. 1-3. Dr. Ralph A. Reis, 104 South Michigan Boulevard, Chicago, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 2-3. Dr. Lawrence D. Thompson, 3720 Washington Boulevard, St. Louis, Secretary.
- Delaware, Medical Society of, Dover, Oct. 9-10. Dr. William H. Speer, 917 Washington Street, Wilmington, Secretary.
- Indiana State Medical Association, Indianapolis, Oct. 9-11. Mr. T. A. Hendricks, 23 East Ohio Street, Indianapolis, Executive Secretary.
- Inter State Postgraduate Medical Association of North America, Philadelphia, November 5-9. Dr. W. B. Peck, 27 East Stephenson Street, Freeport, Ill., Managing-Director.
- Omaha Mid-West Clinical Society, Omaha, Oct. 29-Nov. 2. Dr. Joseph D. McCarthy, 107 South 17th Street, Omaha, Secretary.
- Pacific Coast Society of Obstetrics and Gynecology, Oakland and Del Monte, Calif., November 21-23. Dr. Clarence A. De Puy, 230 Grand Avenue, Oakland, Secretary.
- Southern Medical Association, San Antonio, Texas, November 13-16. Mr. C. P. Loran, Empire Building, Birmingham, Ala., Secretary.
- Virginia, Medical Society of, Alexandria, Oct. 9-11. Miss Agnes V. Edwards, 1200 East Clay Street, Richmond, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Electrocardiographic Observations on Carotid Sinus Reflex. L. H. Sigler, Brooklyn.—p. 782.
- *Action of Quinine and Quinidine on Patients with Transient Ventricular Fibrillation. S. P. Schwartz and A. Jezer, New York.—p. 792.
- Venous Pressure in Thyroid Dysfunction. J. S. Golden and W. A. Brans, Chicago.—p. 802.

Electrocardiogram in Coronary Occlusion Complicated by Pericarditis.—Barnes states that the electrocardiograms of patients in whom acute coronary occlusion is complicated by pericarditis differ from the type of RST changes associated with uncomplicated, acute coronary occlusion. The typical feature of the electrocardiogram, seen in coronary occlusion associated with pericarditis in its early stages, consists of elevation or upward rounding of the RST segment in all leads. This may be followed by inversion of the T wave in all leads. In some instances it is followed by the development of a T pattern that can be classified definitely as a late relic of acute coronary occlusion. In the stage when the RST segment is elevated in all leads, the Q pattern may be typically developed, not only indicating infarction but also pointing to the situation of the infarct in the left ventricle.

Effect of Anoxemia on Electrocardiograms.—Katz and his associates found that the induction of generalized anoxemia in normal subjects produced a diminution in the amplitude of the T wave, at times leading to its inversion. At the same time the ST segment was depressed and at times became negative. Similar changes were produced by generalized anoxemia in patients suffering from angina pectoris. These electrocardiographic changes occurred without the appearance of anginal pain in the normal subjects and in four of six patients suffering from angina pectoris. However, two of the six patients with angina pectoris did develop typical mild anginal pain. The authors therefore conclude that some process in addition to anoxemia (or ischemia) is concerned in the production of the pain of angina pectoris. This process is a variable which prevents the accurate prediction of the occurrence of pain during induced anoxemia. Because of the variability in the results and of the hazard to the patient, the use of induced anoxemia as a test for the presence of angina pectoris is of questionable value.

Quinine and Quinidine in Ventricular Fibrillation.—Schwartz and Jezer administered quinine dihydrochloride and quinidine sulphate intravenously in graded doses to two patients with auriculoventricular dissociation who were subject to tran-

sient seizures of ventricular fibrillation. The drugs were injected when the basic idioventricular rate did not vary more than five beats per minute over a period of several hours prior to their use and when premature ventricular beats interrupted the basic rhythm. The number of these was counted for each minute during the hour preceding the injections. The tests were carried out at a time when it was definitely known that the patients had been free from syncopal seizures for at least twenty-four hours prior to the injections of the drug. Such patients with transient seizures of ventricular fibrillation responded variably to the same dose of both quinine dihydrochloride and quinidine sulphate at different times. The intravenous administration of small doses of quinine dihydrochloride (maximal dose $1\frac{3}{4}$ grains, or 0.11 Gm.) and quinidine sulphate (maximal dose one-third grain, or 0.02 Gm.) resulted in the development of either a prefibrillatory mechanism or transient periods of ventricular fibrillation within from one to nine minutes after the injection. Once the prefibrillatory mechanism is precipitated by the administration of the drug, recurrent periods of transient ventricular fibrillation may follow for several hours at a time. The intravenous injection of these drugs resulted in a more rapid appearance of ventricular fibrillation when premature ventricular beats were already present prior to the onset of the experiment. Since the intravenous use of these drugs precipitated transient periods of ventricular fibrillation in patients who are subject to such seizures, the use of such drugs by this method is contraindicated in such patients.

- Tumors of Breast Related to Estrin Hormone. C. F. Geschickter, D. Lewis and C. G. Hartman, Baltimore.—p. 828.

Experimental Alteration of Malignancy.—Casey carried out experiments to determine whether a homologous tumor material that enhanced every observed phase of the rabbit tumor following intratesticular inoculation would have similar effects following intracutaneous inoculation into the flank. Groups of rabbits injected in the skin of the flank with the material and inoculated into the same or neighboring areas two weeks later with tumor were compared with control groups inoculated with the tumor alone. The results for the control animals confirmed previous experience that the rabbit tumor, although malignant following intratesticular inoculation, is a spontaneously regressing, nonmetastasizing growth following intracutaneous inoculation into the flank. Nevertheless, in the experimental animals treated with the homologous material a higher incidence of and more rapidly growing and lingering local tumors occurred. Distant metastases were discovered in a large proportion of the animals. The preserved material, in enhancing both the primary and the metastatic phases of the malignant change, is therefore not dependent on intratesticular inoculation and is able to overcome the natural resistance of the skin of the rabbit to this tumor. Sex and immaturity are not barriers to the action of this material.

Bone Formation in Metastases of Osteogenic Sarcoma.—Harding and Courville report a case in which all the metastatic foci of osteogenic sarcoma contained bone in a developmental or adult form. In the liver and the lungs some portions of this osteoid tissue were heavily impregnated with calcium, either distributed regularly, as in the case of adult bone, or deposited irregularly in excess, as is common in

abnormal calcification. The nodule in the occipital lobe, which had been roentgenographically visible, contained an abundance of calcium. The nodule in the left central region, separated from the bone by an intact dura and pia-arachnoid, revealed only the earliest evidences of calcium deposit, although osteoid tissue was more or less evenly and abundantly distributed throughout the entire mass. The greater abundance of calcium in the nodule in contact with dura and bone would seem to favor Grieg's view to the extent that a local source of calcium facilitates the process of adult bone formation even though it is not entirely necessary. This nodule was slightly larger and was probably the older of the two.

Menstrual Disturbances of Endocrine Origin.—From a study of sixty cases of menstrual disturbances of endocrine origin, Elden states that it is obvious that there is no relation between the type of menstrual disturbance and the endocrine gland involved primarily. Often an impression from the history as to the gland involved primarily is wrong, as is borne out when the case is studied thoroughly. Diagnosis of menstrual disturbances should not be made on laboratory observations alone. One needs only to consider that a low basal metabolic rate may be due to either thyroid or pituitary. A low blood sugar content may be due to the suprarenals or the pancreas. Hypothyroidism and hyposuprarenalism are at times similar. It is therefore necessary to get all the clinical, physical and laboratory data together in order to establish a diagnosis. The subsequent course of the patient on specific therapy is the criterion of correct diagnosis. In order that menstrual disturbances may be treated correctly, the whole endocrine

system should be investigated before treatment is instituted. Treatment is directed at the involved gland and varies according to the nature of the disturbance.

Pupillary Sign in Ruptured Ectopic Pregnancy.—During the course of the routine physical examination of a patient suspected of having a ruptured ectopic pregnancy, Salmon noticed a unilateral dilatation of the pupil. At laparotomy about a liter of fresh blood was found in the peritoneal cavity and the bleeding traced to a ruptured tubal ectopic gestation. After operation the pupils were found to be equal in size and remained so throughout the patient's convalescence. At the time of admission it was noted that the patient complained of severe right shoulder pain, and it was felt that the dilated pupil might, like the shoulder pain, be caused by the intra-abdominal hemorrhage. Accordingly, during the following ten months the pupils were carefully examined in all patients suspected of having an ectopic pregnancy. During this period sixteen patients with ruptured ectopic pregnancy were operated on, and in four of these, preoperatively, a unilateral dilatation of the pupil was noted, the dilatation disappearing in all cases after operation. In the four patients that had manifested a dilated pupil, shoulder pain was a prominent symptom. However, the dilated pupil and the shoulder pain were not always on the same side.

Drug Idiosyncrasy and Agranulocytic Angina.—In Fitz-Hugh's series of twenty-six patients, seventeen are known to have ingested amidopyrine just before and/or during the disease. A few well established negative instances, however, prove that amidopyrine cannot be accepted as the sole cause. Some of these nonamidopyrine cases may possibly be caused by idiosyncrasy to other drugs and substances (quinine, dinitrophenol, orthiodoxybenzoate, neoarsphenamine, bacterial vaccine) or to a similar abnormal reaction (anaphylactoid) to foods, exogenous or endogenous toxins whether chemical or bacterial, or hormone substances or a conditioned deficiency. If the causal mechanism is of idiosyncratic or allergic nature, it must represent a special blood and bone marrow sequence of events heretofore unrecognized and different from the ordinary clinical and hematologic phenomena usually ascribed to such mechanism. From the standpoint of leukocyte behavior the mechanism seems to be more like that of acute anaphylactic shock in laboratory animals than human allergy. The therapeutic implications of the author's observations suggest the advisability of more specific attempts at elimination and detoxification, especially with regard to the liver as a possible seat of allergic disturbances.

Periarthritis Nodosa and Rheumatic Heart Disease.—Friedberg and Gross observed a significant association of periarthritis nodosa with rheumatic heart disease. Of eight cases of typical periarthritis nodosa verified at necropsy, four presented evidence of rheumatic heart disease: a history of rheumatic fever and the clinical observation of rheumatic cardiovascular disease. Postmortem examination revealed characteristic gross and histologic features of rheumatic fever, including the presence of Aschoff bodies in every case. In addition to the eight cases, the diagnosis of periarthritis nodosa was made in five other cases at postmortem examination, two of which presented clinical evidence of rheumatic valvular disease. Postmortem examination revealed a verrucous endocarditis of the mitral valve in both cases and a large thrombotic mass involving an aortic commissure in one of them. Both cases ran the febrile course of a general infection accompanied by clinical evidences of glomerulonephritis. The evidence in the literature for the association of rheumatic fever and periarthritis nodosa is only of suggestive value. Aside from their four cases the authors have been unable to discover

any others in which there was unquestionable rheumatic heart disease associated with periarthritis nodosa. It seems probable that many cases of periarthritis nodosa previously reported might have been regarded as presenting rheumatic cardiac lesions had they been studied from this point of view. In three of the four cases the symptoms of the final illness were due both to an acute attack of rheumatism and to the lesions of periarthritis nodosa. In the fourth case there were no obvious evidences of active rheumatic infection. Nevertheless, an acute rheumatic lesion was found in the heart. They conclude that they were not dealing with two unrelated diseases but that the periarthritis nodosa was one of the manifestations of the rheumatic infection. In two cases an attack of scarlet fever occurred within eight weeks preceding the final illness. Because of the brief interval between the attack and the obvious development of rheumatic heart disease as well as periarthritis nodosa, it may well be conjectured whether scarlet fever did not stand in some etiologic relationship to these diseases. This association could be employed to reason that not only the rheumatic fever but the periarthritis nodosa was intimately associated with the preceding infection by the scarlatinal organism. In one case, in addition to the periarthritis, the clinical and pathologic features of malignant nephrosclerosis were added to those of rheumatic fever. Fahr maintained that malignant sclerosis is the result of the activity of one or more of several toxic or infectious agents. In two cases the abdominal symptoms, so common in periarthritis nodosa, dominated the clinical picture sufficiently to lead to an exploratory operation. The authors suggest that, when acute abdominal symptoms are present in a patient suffering from rheumatic fever, complicating periarthritis nodosa should be considered. This complication is offered as an organic basis for some of the instances of so-called abdominal rheumatism.

Cardiac Output in Relation to Cardiac Failure.—Harrison and his associates studied the cardiac output of patients with cardiac disease by the acetylene method, modified in such a way as to allow the detection of inaccurate results. The cardiac output per minute of patients with congestive heart failure is usually from 10 to 30 per cent less than that of normal subjects but may be within the normal range. Patients without circulatory disorders may have an equally low cardiac output. The level of the cardiac output per minute, whether considered as such or in relation to the metabolic rate, bears no relation to the presence or absence of congestive failure, for: 1. The range and the average values of the cardiac output are similar for compensated and decompensated patients. 2. In a given individual, clinical improvement and disappearance of congestive phenomena may be associated with an increase, a decrease or no change in this function. In general, the output of the heart per beat tends to be somewhat less during congestive failure. The metabolic rate is normal in some patients and elevated in others. The authors interpret these observations as indicating that the "forward failure" (diminished output) hypothesis, which ascribes the clinical manifestations of congestive heart failure to an insufficient supply of blood to the tissues, is erroneous. They discuss the "backward failure" (back pressure) theory and conclude that there is much evidence in favor of it and no valid evidence against it.

Curability of Hay Fever.—Walker states that preseasonal treatment for hay fever offers a cure, provided the proper pollen extract is used, careful tests are made, and judgment is employed in the manner of treatment. Of the author's 734 patients who received treatment preseasonally for various periods ranging from one to eight seasons, 190, or 26 per cent, have remained free from hay fever. To this number might be added sixty-eight more who are on trial and who are anticipated to remain free from hay fever, to make the total 258, or 35 per cent. Since the largest number of failures occurred after one season of treatment, only half as many after the second season and half as many after the third season as after the second, it is evident that many failures following one season of treatment would result in benefits after a second season, and the same for the third season, provided treatment was continued. The largest number and likewise the highest percentage of cases of permanent relief followed treatment that was given for three, four, five and six successive seasons. The most marked diminution in the cutaneous reaction occurred in

these groups, although the patients who were treated only one or two seasons ran a close second. Of the 190 patients who have remained free from hay fever since the omission of treatment, eight have been free for three years, thirty-one for four years, seventeen for five years, twenty-five for six years, six for seven years, twenty-two for eight years, three for nine years, forty for ten years, twenty for eleven years, eight for twelve years and ten for thirteen years, and all are still free from hay fever.

Renal Glomerulus in Various Forms of Nephrosis.—Wilbur made a histologic study of the glomeruli in kidneys in cases of simple nephrosis in which the diagnosis was made post mortem. Ten cases of acute simple nephrosis presented distinct glomerular changes consisting primarily of irregular thickening of the glomerular basement membrane and less often of an increase in the number and swelling of the endothelial and epithelial cells of the tufts. In the majority of cases these changes were considered independent lesions, the result of associated hypertension, arteriosclerosis or other complicating renal disease. They did not resemble the lesions seen in cases of clinical glomerular nephritis. In thirty-one cases of acute simple nephrosis the glomeruli showed, as a rule, normal tufts with occasional minor variations consisting of variable amounts of debris, usually granular, in the capsular spaces, swelling, degeneration, a slight increase in the number of the endothelial or epithelial cells of the tufts and occasionally slight, irregular thickening of the glomerular basement membrane. These changes were probably degenerative and not suggestive of or similar to those observed in cases of glomerular nephritis or lipid nephrosis. In thirteen cases of bile nephrosis in which the diagnosis was made at necropsy, the majority occurred in persons in whom the glomeruli appeared normal histologically, although a moderate amount of granular material was often noted in the capsular spaces. In six of these cases, slight swelling or proliferation of the endothelial cells of some of the tufts was observed. The epithelial cells of the basement membrane appeared normal essentially. These changes were slight and could not be correlated with the clinical observations. In three cases of chemical nephrosis the glomeruli appeared normal except for congestion, desquamation of many of the epithelial cells and granular material in the capsular spaces. The glomerular changes observed in two cases of eclampsia were similar to those described by Bell. In one case of hyperemesis gravidarum the glomeruli appeared normal, although granular material was noted in the capsular spaces. The renal lesion in eclampsia is probably secondary and, although it is distinct and probably degenerative, its nature cannot be stated at present.

Histologic Changes in Knee Joint in Various Infections.—Keefer and his co-workers studied the pathologic lesions of eight cases of infective arthritis due to streptococcus, gonococcus, meningococcus and pneumococcus infections and to an unidentified gram-negative coccus. The character of the change varied with the mode of infection, which occurred by way of the blood stream, by direct extension from an osteomyelitis or by direct extension from the skin overlying the joint. In the cases in which the infection of the joints occurred as a result of a hematogenous infection, the process began in the synovial connective tissue, with infiltration of polymorphonuclear, lymphoid and plasma cells about the blood vessels and between the strands of connective tissue. As the infection progressed, the synovial lining was destroyed and replaced completely by granulation tissue. Later the cartilage and bone were involved in the process and destroyed. When the bone was involved

primarily, the predominating lesions were a destruction of bone and the overlying cartilage. The inflammation of the synovia showed a progression from the superficial to the deeper layers. The changes were characteristic of an inflammatory process and could be distinguished readily from degeneration. Aside from the mode of infection, the type of infecting organism, the effect of pressure, the character of the cellular reaction and the presence of antiferment substances in the synovial fluid determine the final pathologic state.

Generalized Torulosis Associated with Hodgkin's Disease.—Fitchett and Weidman report a case of generalized torulosis associated with Hodgkin's disease. The presence of extensive renal involvement calls attention to the necessity for examination of the urine for torula cells as they have been observed in the urine at least once. Attention is called anew to the possibility that the intestine may serve as the primary portal of entry for torulosis. Cases of Hodgkin's disease showing meningeal symptoms demand examination for torular infection.

Comparison of Media Used in Presumptive Tests for Bacterium Coli.—In comparing certain media used in presumptive tests for Bacterium coli, Horwood and Heifetz found lactose broth to be the most sensitive when freshly isolated strains of fecal Bacterium coli were used. Brilliant green lactose peptone bile was second, the Dominick and Lauter medium third, and Salle's crystal violet lactose broth fourth. When suspensions of Bacterium aerogenes in water were employed, the same media were equally sensitive. When the waters were examined, lactose broth again proved to be the most sensitive presumptive test medium, with brilliant green lactose

peptone bile showing almost the same degree of sensitivity. The other media were less satisfactory. The Dominick and Lauter medium yielded the greatest proportion of completed tests and the brilliant green lactose peptone bile was almost as good. Numerically, brilliant green lactose peptone bile yielded more completed tests than any other medium. The superior results obtained with lactose broth as a presumptive test medium cannot be explained necessarily on the ground that it is more susceptible to spurious presumptive tests. The inferior results obtained with the other media may be due to the inhibition or destruction of the so-called weaker strains of Bacterium coli, which may have sanitary significance. In view of this possibility, lactose broth still seems to be the best presumptive test medium available. Efforts to improve its effectiveness by suitable buffering, by shortening the period of incubation and by other means should be made before it is abandoned. The excellent results obtained with brilliant green lactose peptone bile indicate its value in the sanitary water analysis.

Antibody Formation After Extirpation of Antigen Depot.—Cannon and Burt made an attempt to determine the way by which the bacteria left the site of injection. The ears of rabbits, amputated within eight seconds after injection of a heavy suspension of staphylococci, were sectioned and stained with eosin-azure. Large masses of bacteria were seen in the loose subcutaneous tissues round blood vessels and a few bacteria were visible within the lumens of veins. Occasional cocci were seen also in lymph canals, but for the most part the micro-organisms appeared to seep into the veins and in that way became dispersed throughout the body. These observations furnish morphologic support to the conclusions reached by Roberts. Postulation of a new mechanism for the production of antibody after the removal of the antigen depot is

unnecessary, at least until proof is available that antibody formation may occur independently of the escape of antigen from the original depot.

Calcium in Blood and Cerebrospinal Fluid.—Katzenelbogen carried out studies in cats before and after the administration of bulbocapnine and also in human beings with low and high bromide contents in the blood. The observations show that it is the diffusible serum calcium that chiefly makes the decrease of the total blood calcium during bulbocapnine intoxication. The distinct changes in the diffusible part of the blood calcium, however, do not reflect on the calcium content of the cerebrospinal fluid, although symptoms of intoxication are marked. The calcium studies in cats before administration of bulbocapnine and those in human beings with low bromide concentration in blood show that in normal conditions the content of cerebrospinal fluid calcium is essentially equal to the content of diffusible calcium in the blood. The observations in both bulbocapnine intoxication in cats and in human beings saturated with bromide suggest that intoxication is apt to alter the normal balance of equality between cerebrospinal fluid calcium and diffusible blood calcium. Such alteration appears to be caused primarily by a drop in the diffusible blood calcium, as seen in the bulbocapnine experiments.

Effect of Dinitrophenol on Circulation Time.—Freeman gave nine male schizophrenic patients showing no apparent organic disease dinitrophenol (1-2-4) in amounts of from 3 to

5 mg. per kilogram of body weight daily for seven weeks. These amounts were sufficient to raise the oxygen consumption rates a mean of 28 points, resulting in a significant mean decrease in the circulation time of 6.2 seconds. A new level having been reached, no further variation in the circulation time was observed with an increase in the oxygen consumption.

Intravenous Administration of Dextrose in Asthma.—Lepak treated four cases of bronchial asthma secondary to an infection of the upper respiratory tract by the intravenous administration of a 50 per cent solution of dextrose. The best results were obtained in the bedridden patients with 100 cc. of the dextrose solution given consecutively for two or three days. In the ambulatory type of patient, 50 cc. of the solution administered for several days gave encouraging results. A concentrated solution relieved the intensity as well as the frequency of the asthmatic attacks. The attacks of asthma sometimes were relieved completely for several months. The solution was heated to 95 F. to avoid constitutional reaction. This solution was administered slowly by syringe through a medium sized needle. Placing the arm in a horizontal position or even slightly lower than the forearm will aid in preventing the coagulation of blood in the vein. Occasionally, during the last part of the administration the patient may complain of soreness in the arm. The pain follows the course of the vein and is undoubtedly due to an irritation of the venous wall by the concentrated dextrose solution. It is possible that less concentrated solutions may give the beneficial pulmonary results and yet reduce the local danger of a thrombosis or phlebitis.

- Diabetes and Cancer.**—Marble made an analysis of 256 cases in which malignant disease and diabetes were associated. These represent cases recognized among 10,000 diabetic patients.

Among the fatal cases, the average duration of diabetes was 7.1 years. The average duration of symptoms of cancer was 1.8 years. The conclusion is drawn that, in general, cancer develops in the diabetic patient and not diabetes in the patient having cancer. Evidence is lacking that cancer brings about the diabetic condition. A study of available data shows that the increasing percentage of cancer deaths to total deaths during the last two decades is greater among diabetic patients than among members of the general population. This is thought to be due, in part at least, to the fact that the increased longevity of diabetic patients during the last decade has placed relatively more diabetic than nondiabetic persons in the cancer age zone. It does not necessarily imply that the diabetic patient is any more likely to develop cancer than the nondiabetic person. The author's series includes thirty-three cases of carcinoma of the pancreas, of which twenty-one were diagnosed either at operation or at necropsy. The incidence of carcinoma of the pancreas was therefore extraordinarily high. It was 12.9 per cent of the total number of cases as contrasted with less than 5 per cent in the general cancer statistics reported by others. The average duration of symptoms of cancer in the twenty-one proved cases of carcinoma of the pancreas was one year; in these cases the average duration of diabetes was 3.4 years. The latter figure represents the shortest duration of diabetes of any group of diabetic patients under observation. Thus a possible relationship between cancer of the pancreas and diabetes is suggested. Figures from the literature, however, tend to indicate that diabetes is relatively uncommon in cases of carcinoma of the pancreas.

*Experimental Lymphocytic Choriomeningitis of Monkeys and Mice Produced by Virus Encountered in Studies of 1933 St. Louis Encephalitis Epidemic. C. Armstrong and R. D. Lillie.—p. 1019.

Lymphocytic Choriomeningitis Produced by Virus of St. Louis Encephalitis Epidemic.—Armstrong and Lillie describe a virus that was encountered during monkey-to-monkey transfer of infection from a patient who died during the 1933 St. Louis epidemic of encephalitis. From the patho-

logic picture produced by intracerebral inoculation of monkeys and mice, they designate the virus as the virus of experimental lymphocytic choriomeningitis. It is apparent to the authors that the virus is distinct from the 1933 St. Louis encephalitis strains for the following reasons: 1. Cebus monkeys and guinea-pigs refractory to encephalitis strains succumb to the choriomeningitis strains. 2. The usual incubation period of from four to ten days in monkeys is shorter than is usual with encephalitis strains (from eight to fourteen days). In white mice the reverse is true: from six to nine as compared to from four to eight days with the encephalitis virus. 3. Infected monkeys are less tremulous, less excitable, less active, more prone to refuse food and appear much more ill than do encephalitis-infected animals, while in white mice the more pronounced tremors, which pass into a striking tetanic, often fatal, convulsion, not observed in encephalitis mice, offer a striking contrast. 4. The virus is almost constantly found in the blood and spinal fluid of monkeys during the febrile stage, while the encephalitis virus has not been demonstrated in these fluids during this period. 5. The choriomeningitis virus fails to produce detectable symptoms in mice when introduced intranasally, while the encephalitis virus takes readily by this route. 6. The changes produced by the two viruses in mice and monkeys is usually readily distinguishable. 7. Cross neutralization tests indicate that the viruses are immunologically distinct. Furthermore, the choriomeningitis virus does not correspond in its characteristics with those described by various Japanese investigators who have reported the isolation, usually in rabbits, of strains of virus from cases occurring during the outbreaks of encephalitis in Japan, which were epidemiologically and clinically quite similar to that of St. Louis. 8. The virus does not possess the characteristics of a herpes virus; moreover, rabbits inoculated intracerebrally with the choriomeningitis virus without apparent results readily succumbed to intracerebrally administered herpes virus given thirty-four days later. Neither does it correspond with any described virus of which the authors are aware, for which reason they consider it to be a heretofore undescribed infectious agent of which the significance in nature is at present unknown.

Peripheral Vasodilating Effect of Theobromine.—

Encouraged by the vasodilatation following the intravenous administration of theobromine, Newell and Allen made studies on the response of the temperature of the skin to the oral administration of theobromine. Twenty experiments were done on fifteen patients with thrombo-angiitis obliterans or thrombo-arteriosclerosis obliterans. The response of the cutaneous temperature to the oral administration of theobromine was less than 1 degree in five instances, and between 1 and 2 degrees C. in seven instances. There were only eight instances in which the increase in temperature of the skin exceeded 2 degrees C. Comparison was made with the vasodilatation following artificial induction of fever by the intravenous injection of typhoid vaccine in thirteen instances. The average increase in the temperature of the skin caused by theobromine was 1.8 degrees C., while that caused by artificially induced fever was 4.2 degrees C. The average duration of the increase in the temperature of the skin following the ingestion of theobromine was two hours. In this regard the drug is much less efficient than typhoid vaccine intravenously injected, for the vasodilatation induced by the latter ordinarily lasts for many hours. The oral administration of theobromine may be of some value in instances in which it is inadvisable to use methods of greater value (typhoid vaccine, sympathectomy). It may be used as an adjunct to these methods of treatment.

Calcification of Gallbladder.—Snodgrass reports a case of calcification of the gallbladder in which calcification of the whole wall occurred and in which only two large stones were present, one of which completely blocked the cystic duct. The final diagnosis was cholelithiasis, cholecystitis and calcification of the wall of the gallbladder. Robb believes that, if contraction and pressure atrophy can cause a calcification, a simple dilatation atrophy can do the same. He cites a specimen in which the gallbladder was markedly dilated and the cystic duct was blocked by only one gallstone. He explains the calcification on the basis of a blockage, resulting in a mucocele with consequent distention, loss of function leading to atrophy in the muscular strata, fibrous replacement and finally calcification. Calcification has taken place in the wall and the duct round the gallstone, and similar to the author's case the part of the cystic duct lower down remained normal, indicating, as Robb believes, that the stress of dilatation and of contraction and pressure atrophy are the chief causal factors in the calcification.

Medicinal Treatment of Chorea.—Mutch believes that calcium acetylsalicylic acid (calcium aspirin) possesses the means of dealing simultaneously with the three etiologic factors of chorea: rheumatism, nervous strain and calcium deficiency. It supplies an adequate amount of calcium, produces a useful sedative effect on the brain, and combats the rheumatic element if given in appropriate doses. It dissolves readily in water (1 Gm. dissolves in 5 cc.) and forms a neutral solution suitable for administration by vein or subcutaneously, as well as by mouth. By crystallization from a solution of calcium chloride a form of calcium acetylsalicylic acid is obtained with a stability approximately equal to that of the parent acetylsalicylic acid itself. The author's nineteen patients were kept in bed. A light, mixed diet was given. The only drug employed (exclusive of aperients) was calcium acetylsalicylic acid (Coplans), dissolved in water and administered by mouth. The average daily dose varied up to 45 grains (3 Gm.) for a child 12 years of age. The rapidity of response did not vary accurately with the original severity of the choreic movements; mild cases sometimes proved more resistant than severe ones. The attack was not registered as over until the condition had so far improved that an average medical man would have had difficulty in diagnosing the case as one of chorea. Spontaneous movements had ceased. Voluntary movements were of average accuracy, and the patient could sustain a steady grip of the hand for a minute or more without fluctuation. The average time taken to control the chorea was seventeen days, and the limits were seven to forty-six days, respectively. The drug diminished the discomforts of the patients at all stages of treatment and did not produce any mental depression, undue drowsiness or digestive derangement. There was no relapse or secondary exhaustion when the drug was withdrawn finally.

Rupture of Membranes in Treatment of Eclampsia.—

Stroganoff advocates early rupture of membranes in the treatment of eclampsia. By the early rupture he means rupture when the os is closed or not larger than 2 inches. The membranes should not be ruptured in the transverse position or in the presentation of the cord. Rapid delivery followed rupture of the membranes. Even when labor had not commenced, delivery occurred within an average of twenty-two hours and six minutes. There were seventy-four primiparous and twelve multiparous patients. The reduction in the number of fits following the rupture of membranes was unexpected. In fifty of eighty-seven cases not a single fit was observed to occur prior to delivery following rupture of the membranes. Of this number three patients had fits subsequent to delivery. In preeclamptic cases the effect of the operation was also favorable: only two of six patients had fits prior to delivery and the other four had fits only after delivery. The author believes

that the favorable results obtained by early rupture of the membranes may be explained by a number of theoretical considerations. Following the discharge of from 150 to 400 cc. of the amniotic fluid, the uterus becomes smaller and the pressure in it is lessened and, further, the absorption of the amniotic fluid containing certain ferments and extractive substances into the mother's circulation is thus reduced. Together with the decrease in the size of the uterus, the contents of the abdominal cavity are also reduced in volume and the intra-abdominal pressure in it is lowered, at least for a certain period of time, which results in the abdominal organs being better supplied with blood. The diaphragm descends somewhat lower and its excursions become less restricted, oxidation of the blood is improved and all the organs of the body, and especially those of the abdominal cavity, come under better conditions of nutrition and respiration. The heart is also under more favorable conditions. The changes are small, but their importance cannot be denied. It may be that nervous and, especially, vasomotor reactions due to the rupture of membranes, with all its consequences, are of still greater importance. The author believes that an insufficient oxygen content in the blood is a most important factor in the development of severe eclampsia. The technic consists in dilating the cervical canal and then rupturing the membranes. When the os admits one finger or more, the use of dilators is unnecessary.

Vesicovaginal Fistula.—Ratnayake presents a case of vesicovaginal fistula resulting from ulceration of a prolapse. Under open ether, the vaginal mucosa was raised off the bladder by the flap method, much difficulty being experienced owing to thick cicatricial tissue. The vesical wall with the fistula was exposed. The fistula, being small, was closed with a purse string of fine silk. The vaginal mucosa was approximated by a continuous catgut suture. A self-retaining catheter was introduced and continued to be used for seven days. The patient made a good recovery. The secondary operation for repair of the perineum was undertaken two weeks later with an uneventful convalescence. The author stresses the following points of the case: 1. Ulceration of a prolapse due to friction from clothing had extended so deeply at one spot as to involve the vesical wall and mucosa, resulting in the formation of a fistula. 2. The patient passed small quantities of urine frequently and was not conscious of the dribbling, except as what she called a watery discharge. 3. Healing of the ulceration produced sufficient cicatrization and shortening of the anterior vaginal wall to cure the prolapse partially. 4. The existence of the fistula was detected almost by accident. Failure to detect it would have resulted in an unsatisfactory operation for repair of the pelvic floor with leakage of urine interfering with healing. The value of a preliminary cystoscopic examination before repair of the pelvic floor is undertaken is stressed. Pyelography is invariably carried out at some clinics to eliminate the existence of kinking of a ureter and hydronephrosis.

Pain of Herpes Zoster Treated with Solution of Pituitary.—Gillett presents three cases in which solution of pituitary was used for the treatment of herpes zoster. He has found that the injection of solution of pituitary is an uncertain and by no means an infallible treatment. It appears to act most dramatically when the pain is most intense. He can at present offer no explanation of why this should be so, but the treatment is a valuable asset to the practitioner in his attempt to relieve a patient from the pain accompanying herpes zoster.

Rare but Clinically Important Conditions.—Linnell and Dunlop discuss conditions that almost never occur in the experience of an average practitioner but that are worthy of serious consideration as being of surpassing interest. Chronic pulmonary tuberculosis of the adult type almost never occurs in young children. In disease of the cardiovascular system the mitral valves are almost never merely retracted through the effects of rheumatic endocarditis so as to cause a wider aperture than usual and thus simple regurgitation. Pain in the right side accompanied by marked pyrexia is almost never, if ever, due to acute appendicitis, if there have been rigors. The victim of a sudden perforation of the stomach or intestine is usually seized with excruciating abdominal pain and lies remarkably still. Retention of urine is not uncommon in hysterical states. Incontinence, on the other hand, in adult life, is almost never encountered in "functional" disorders and should always be looked on as a sign of organic disease affecting the central nervous system. A patient suffering from acute arthritis with fever, who is not considerably better after forty-eight hours of treatment by full doses of salicylates, almost certainly does not have rheumatic fever. Addison's disease should never be diagnosed in the presence of a high or even normal blood pressure. Almost never is the systolic blood pressure in Addison's disease, when diagnosable, above 100 mm. of mercury. A rash that itches to any degree is almost never syphilitic. A pustular rash that involves the trunk more than the face, the wrists and the hands is almost never due to smallpox. A malarial patient, continuously resident two years in a nonmalarial country, almost never suffers from malaria, however much he may protest to the contrary. The connection between acute rheumatism and erythema nodosum has never been proved, though till comparatively recently it has been generally accepted. Whatever its cause or causes may be, one thing is certain: almost never, if ever, does endocarditis result; it runs its course, whatever treatment is given, and clears up without sequelae. A "breakdown" is almost never due to overwork, so long as both work and environment are congenial. An unpleasant situation is almost always present and is to be looked for.

Fractures of Anterior Edge of Lower Extremity of Radius.—Rousseau and Adamesteanu consider fractures of the anterior edge of the lower extremity of the radius with the preceding carpal subluxation that accompanies it a rare condition but a clinical entity that one is justified in studying. The exact etiology is uncertain, though it is a condition of adults. It has been reproduced experimentally on the cadaver by increasing the push of the anterior surface of the horizontally placed scaphoid against the anterior articular margin of the radius. The diagnosis is not impossible to make clinically but should have roentgenologic confirmation. Treatment in recent cases consists in rapid mobilization of the articulation to avoid joint stiffness. When combined with carpal subluxation, the deformity must first be reduced under general anesthesia. In old cases nothing is to be hoped from orthopedic treatment. Surgical intervention by the anterior route with osteotomy of the callus, reduction of the luxation and replacement of the detached fragment in good position must be done.

Instability of Glycemia in Diabetic Children.—Mauriac and Traissac report the cases of two diabetic children in whom a narrow margin existed between hyperglycemia and hypoglycemia and insulin shock. In both children (aged 3 and 7 years) glycosuria of several grams continued in spite of a diet of 120 Gm. of carbohydrate and 20 units of insulin, and 150 Gm. of carbohydrate and 18 units of insulin, respectively. In both, also, the smallest increase in insulin or the slightest decrease in carbohydrates sufficed to cause hypoglycemic symptoms. If, on the other hand, the insulin was reduced as little as 2 units the glycosuria increased markedly and was accompanied by signs of diabetes-polyuria, thirst and asthenia. This syndrome has been encountered by the authors only in infantile diabetes. They believe that the disorder thus revealed is essentially one of regulation and illustrates the complex neuroendocrine-sympathetic origin of such diabetes.

Modified Sippy Treatment of Gastric Ulcer.—Albrecht states that a modified Sippy treatment has been employed for the past several years at the medical clinic in Zurich. He gives a tabular outline of the method which indicates that small amounts of food (in the first few days only milk and cream and later additions of solid foods) are given on the full hour from 6 o'clock in the morning until 7 o'clock in the evening inclusive, and he points out that the new procedure differs from the original Sippy treatment in the manner of reduction of the acidity. Attempts are made to decrease the secretion by a belladonna preparation that exerts a favorable influence also on the motility. The acidity of the gastric juice is reduced by the administration of dispersed aluminum hydroxide. These medicaments are administered in such a manner that a measure (approximately from 3 to 4 Gm.) of the aluminum preparation is given at half an hour after 6, 7, 9, 10, 12, 1, 3, 4, and 6 and at 8, and 15 drops of an extract of belladonna leaves at 8:30 and 2:30, and 10 drops of the same substance at

half an hour after 11, 5 and 7. Depending on the condition of the patient, the treatment, which ordinarily is continued for twenty-eight days, may be lengthened or shortened and the doses of the medicaments may be reduced. Some patients, particularly those with constipation, may be given magnesium preparations (magnesium oxide or a mixture of magnesium peroxide and magnesium oxide) instead of the aluminum hydroxide. The preparation of the belladonna leaves may eventually be replaced by the administration of atropine (0.5 mg. three times a day). The patient should be kept in bed during the entire duration of the treatment, and after it has been discontinued a light diet is advisable. The author states that the treatment was employed in 108 cases. He asserts that the results were favorable not only as regards the subjective symptoms but also in that the roentgenologic control revealed the disappearance of many ulcer niches. However, the reduction of the acidity was not quite satisfactory. The acidity values and the other symptoms of ulcer did not always run parallel; at any rate, the part played by the acidity in the genesis of ulcer and its symptoms is not entirely clear as yet.

Carotid Sinus in Mechanism of Acute Pulmonary Edema.—Salmon states that in the area of bifurcation of the primary carotid artery, that is, in the sinus of the internal carotid, there is to be found in the adventitia a rich plexus of nerve fibers covering the carotid sinus itself. The fibers of this plexus meet in a small nerve described by Hering and designated as the nerve of the carotid sinus or Hering's nerve. Its fibers anastomose with those of the glossopharyngeal nerve and the vagus. The carotid plexus presents anatomic connections with the carotid gland situated in the same region. This gland, made up largely of a chromaffin substance, is considered by many anatomists an accessory chromaffin organ. Numerous fibers of the upper cervical ganglion pass to the intercarotid plexus. The region of Hering's "carotid sinus" is a center of special reflexes, in that pressure on the carotid region or its direct stimulation produces bradycardia and peripheral vasodilatation determining a marked lowering of arterial pressure. The center of these reflexes is the carotid sinus, which is anatomically and functionally connected with the bulbar nuclei. These reflexes may be abolished by destruction of the sinus and after resection of Hering's nerve, which is supposed to produce a depressive action on the arterial tension analogous to that of the depressor nerves of De Cyon-Ludwig. The carotid sinus is sensitive to mechanical stimuli, to increase of arterial pressure, to compression and shutting off of the carotid arteries and to chemical and thermic stimuli. The sinus is stimulated by epinephrine, strychnine, calcium chloride, caffeine, atropine, sparteine and other substances. The excitability of the sinus diminishes in suprarenal insufficiency. The author refers to the sympathetic-epinephrine or neurohormone theory of acute pulmonary edema. This theory, he believes, explains the relation of the condition to arterial hypertension. It does not explain why a hypersuprarenalemia of marked sympathetotonic action causes acute pulmonary edema, conditioned by dilatation of the pulmonary vessels and presenting characteristic vagotonic symptoms. The author states that this point is made clear by invoking the part played by the carotid sinuses, which react to sympathetotonic stimuli, particularly to epinephrine. Because of their intimate anatomic connections with the sympathetic nervous system, the bulbar nuclei, the vagus center, the respiratory center and the vasomotor nuclei, they give rise to vagotonic symptoms of bradycardia, fainting, polypnea and dilatation of the pulmonary vessels, the most characteristic symptoms of acute pulmonary edema. The author attributes an important part in the pathogenesis of acute pulmonary edema to the toxic factor (increase of potassium in the blood) and to the pulmonary factor.

Serum Reaction for Diagnosis of Infantile Leishmaniasis.—Auricchio and Chieffi demonstrate that the blood serum of children suffering from leishmaniasis flocculates rapidly on addition of solutions of iron peptonate. They employed the following technic in six children presenting different stages of the disease. The blood is taken from the finger tip of the fasting patient. The amount of serum needed for the reaction is 0.2 cc., for which 0.1 cc. of blood is sufficient. The blood is collected with a pipet having a capillary point. The solution of iron peptonate must be freshly prepared. Three tubes are used. The serum to be examined is put in one tube; the same amount of serum from a normal child or from one affected by a disease other than leishmaniasis is put in another tube for control, and 1 cc. of the solution of iron peptonate at 1:600 is run in the three tubes. These are shaken and placed in a thermostat at 98.6 F. and observed every ten minutes for forty minutes. If the reaction is positive in the test tube containing the serum to be examined, the liquid becomes opalescent and flocculent and precipitates slowly to the bottom of the tube. No change is seen in the liquid of the control tube, the same limpid aspect persisting as in the tube containing only the solution of iron peptonate. Sometimes an opalescence may be observed, which is due to the distilled water of the solution. The reaction was positive in all cases of leishmaniasis. The serum reaction was constantly negative in ten normal individuals, in six patients having congenital syphilis, in eight presenting various clinical manifestations, in two with hemopathies and marked splenomegaly, in ten cases of malaria, in six of favism and two of typhoid, and in three patients presenting acute respiratory diseases.

*Descent of Vertebral Hypophonesis. E. S. Weiler.—p. 700.

New Sign of Pleural Effusion.—Weiler considers Koranyi's sign (hypophonesis of the dorsal segment on direct percussion of the apophysis of the dorsal vertebrae) of diagnostic value in pleural effusion. The mechanism of the sign is explained by the interposition of the pleura, filled with liquid, between the lateral and ventral aspects of the vertebrae and the lung. The sign may also be present without pleural effusion in bilateral hepatization of that portion of the lung adjacent to the dorsal vertebrae and in intrathoracic tumors, when they are in contact with the lateral and ventral aspects of the dorsal vertebrae. To differentiate the presence of pleural effusion from that of either intrathoracic tumors or bilateral hepatization of the lung, the author has determined the hypophonesis of the dorsal segment during the changes of position of the patient. The upper limit of the hypophonesis is verified by means of the direct percussion of the dorsal apophysis and then marked, first with the patient standing or sitting down (classic technic) and then with the patient in abdominal decubitus. In cases of pleural effusion the upper limits of the vertebral hypophonesis descends one, two or more interspinous spaces. The author calls the sign "descent of the vertebral hypophonesis." Its mechanism is explained by the mobilization of the intrapleural liquid, leaving the pleura between the lung and the dorsal and ventral aspects of the vertebrae more or less empty during abdominal decubitus.

When the pleural effusion is not great and there is no hepatization of the lung, the vertebral column recovers its normal resonance along its whole length (positive hypophonetic disappearance). The absence of modifications of the vertebral resonance during the changes of position of the patient (negative hypophonetic descent) indicates an absence of pleural effusion. The sign is not equivalent to Grocco's triangular area and frequently shows itself without the existence of such an area.

Hemagglutination Reaction in Syphilis and Other Infections.—The correct interpretation of an accidental observation led Bachmann to evolve a suitable active method for the serologic demonstration of syphilis, which, like many other tests, is based on Bordet's complement fixation reaction. However, the positive outcome is indicated not by the simple inhibition of the hemolysis but by the agglutination of the sheep corpuscles. It was observed that, if sheep corpuscles in a 2.5 per cent suspension are mixed with concentrated or attenuated hemolysin (immune serum of a rabbit that has previously been treated with red corpuscles of sheep), the sheep corpuscles become agglutinated. If active serum of a syphilitic patient is mixed with attenuated antigen in the form of an alcoholic extract, placed in the incubator for from ten to twenty minutes and mixed with a 2.5 per cent suspension of sheep corpuscles, and if finally the hemolysin is added, a further incubation of thirty minutes duration leaves the hemagglutination in existence; while, if the same test is made with a negative active serum, lysis of the sheep corpuscles is observed. The technic of this hemagglutination reaction is as follows: Into each of three tubes are put 0.1 cc. of serum from the patient and 0.1 cc. of physiologic solution of sodium chloride and 0.2 cc. of diluted antigen in the proportions of 1:4, 1:5 and 1:6, respectively. Incubation lasting from fifteen to twenty minutes is followed by an addition of 0.2 cc. of a 2.5 per cent suspension of sheep corpuscles; finally 0.1 cc. of hemolysin, mixed 1:1 with physiologic solution of sodium chloride, is added. After thirty minutes of incubation the first reading is taken, to be followed by another reading from one to two hours later. A comparison of the results thus obtained in 982 tests revealed conformity between the inactive methods of the Wassermann reaction, the Meinicke turbidity reaction and the hemagglutination reaction in 90.7 per cent of the cases. The author emphasizes that the hemagglutination reaction is a valuable method for the serologic demonstration of syphilis, which has the advantage that the use of guinea-pig complement can be dispensed with and that it can be used in older serums (up to five days old). The reaction requires the previous examination of the hemolyzing or agglutinating immune serums for their suitability. He shows that the test can be used also for the serologic diagnosis of gonorrhea, typhoid and some cases of rhinoscleroma. He describes the technics for gonorrhea as well as for typhoid.

Early Diagnosis of Liver Diseases.—Fischler admits certain factors that make the diagnosis of liver diseases more difficult than the diagnosis of disorders of other organs, but he emphasizes that the negativistic attitude toward the early recognition of disorders of the liver is not justified. He shows that urobilinuria and urobilinogenuria are highly reliable and exact indicators for the existence of functional disturbances of the liver. Careful attention given to these symptoms for many years has convinced him that involvement of the liver in other disorders and disease of the liver itself are unusually frequent. He shows that, in the present status of knowledge, urobilinuria is still largely merely a symptom instead of a completely understood disease process. In answer to the question whether urobilinuria is always a sign of liver disease, he

points out that there is also a physiologic urobilinuria, and in explaining it he discusses the functions of the liver and the factors involved in these processes. He emphasizes that in the evaluation of urobilinuria the functional condition of the liver is of vital importance. Then he gives his attention to the pathologic urobilurias. They are characterized by prolonged duration of the elimination of urobilin bodies, by a considerable height of the urobilin content and by the relative unresponsiveness to antiurobilinuric dietary measures. He takes up in detail the urobilurias observed in febrile conditions, those caused by disturbances in the hematologic system, those accompanying diabetes mellitus, those caused by disturbances in the blood discharge from the liver and those occurring in cirrhosis of the liver, in disorders of the biliary system and in tumors of the liver. In the conclusion he states that he gave his attention primarily to the urobilurias because he considers them the first and most important signs of a disturbance in the function of the liver. He does not wish to discredit the many other functional tests of the liver.

Infection and Toxic Edema.—Busson and Kovacs point out that the failure to demonstrate toxins in certain infections that obviously exert a toxic effect has long been a problem of immunobiology. At present it is assumed that in these instances the toxins are not found within the bacteria or eliminated by the bacteria but are probably formed within the tissues under the influence of the invading micro-organism. Attempts have been made to explain on this basis certain actions of gas gangrene and of some streptococcal and staphylococcal infections. However, since the nature and the chemical composition of the toxins produced within the organism were still obscure, the studies of Eppinger deserved especial attention. That author proved the strong toxic action of the allylamine formates and of related substances on the organism, and their development from organic substances by the action of certain bacteria in the culture medium and their presence in pathologic processes. Moreover, it was possible to demonstrate an apparently specific toxic action of these substances following the destruction of tissues. In view of these observations it appeared logical to investigate what influence is exerted by such amines on the course of an infection. The authors made the following infection experiments with a hemolytic streptococcus strain and a hemolytic staphylococcus strain: They injected into a guinea-pig on the left side of the thorax 1 cc. of an eighteen hour bouillon culture of a hemolytic staphylococcus. An infiltrate developed at the site of injection but gradually disappeared again, and the animal did not die. However, if simultaneously with the bacterial culture 0.05 cc. of acrolein was injected on the right side of the thorax, the animal died within twenty-four hours. It was demonstrated by another experiment that this was due to a local action of the acrolein, to a promotion of the fixation and development of the infection by a localized impairment of the tissue in the form of a serous inflammation, of a toxic edema, and was not the result of a generalized damage by the reduction of the natural resistance of the animal. This experiment was carried out by injecting the acrolein not into the region immediately adjacent to the staphylococcal depot but distant from it, into the gluteal muscle. The result was that the animal remained alive. Experiments with a strain of hemolytic streptococcus produced the same results. The author calls especial attention to the fact that in the animals that died the heart blood contained no streptococci or staphylococci but that the pathogenic

micro-organisms were present in great masses in the region of the toxic edema.

Rôle of Reticulo-Endothelium in Formation of Fibrinogen.—Held and Behr review several theories regarding the site of fibrinogen formation. They mention the liver, the bone marrow, a connection between leukocytosis and fibrinogen content, and finally the spleen and lymph nodes. These theories, most of which are well supported, can be brought into harmony by ascribing the capacity for fibrinogen formation either to all cells or to a type of cell that is present in all these different organs. The first assumption is justified only if localization fails. In regard to the second possibility, a former investigation supposed that the reticulo-endothelium is the common type of cell, since it may be assumed that the reticulo-endothelium has not only decomposing functions but also constructive ones. The authors point out in this connection that the formation of certain blood protein bodies (antibodies) is ascribed to the reticulo-endothelial system, that Bennhold demonstrated the close exchange relations between the blood protein bodies serving as "vehicles" and the reticulo-endothelial system, and that in anaphylactic shock there is a disappearance of fibrinogen and a functional arrest in the reticulo-endothelial system. On the basis of these considerations they decided to make storage experiments on the reticulo-endothelial system with a thorium dioxide preparation, with colloidal copper and with india ink. They describe the outcome and conclude that these experiments furnish the proof for their theory that the reticulo-endothelial system is the source of fibrinogen.

Insulin Destroying Power of Erythrocytes.—Rosenthal and his associates found in studies on erythrocyte suspensions, which were free from leukocytes and thrombocytes, that hemolyzed erythrocytes exert an inhibiting influence on insulin, while intact erythrocytes, under the same conditions, have no damaging effect on insulin. The insulin destroying power of the erythrocytes is due to an endoglobular principle, for the stromas washed free from hemoglobin have no influence on insulin, while a hemoglobin solution that is free from stromas is capable of arresting the action of insulin. The insulin destroying power of hemolyzed erythrocytes can be abolished by keeping them for one hour at 70 C. This thermostability indicates fermentative powers in the erythrocytes which may be identical with the peptide-splitting ferments that Abderhalden discovered in the erythrocytes. Whether the insulin destroying properties of the erythrocytes are of clinical importance for the phenomenon of insulin resistance and for the ferment economy of the erythrocytes will require further investigations.

Tuberculous Pulmonary Infiltrates and Carbohydrate Metabolism in Childhood.—In studies on tuberculous children, von Mettenheim aimed to determine whether the regulation of the sympathetic nervous system is impaired in children with pulmonary tuberculosis, particularly whether the functional activity of the liver is changed. Dextrose tolerance tests were made on eighty-eight children between the ages of 4 months and 13 years. It was found that the blood sugar curves differ from those of normal children and that the various forms of tuberculosis have typical curves. These results are essentially identical with those obtained by Spiro in adults. This author pointed out that the curves greatly resemble those obtained in allergic diathesis. This in turn recalls the opinions of some investigators, who have pointed out that tuberculous infiltrations develop in children with sympathetic diathesis, who have an increased tendency to swell-

ing, a greater reaction capacity of the entire organism and an allergic disposition that may be due partly to a sensitization by repeated infections, and also a functional disturbance of the organs involved in the carbohydrate metabolism, particularly the liver. The majority (thirty-seven out of forty-six) of the children with tuberculous infiltrates, examined by von Mettenheim, presented aspects of exudative diathesis. Consequently he concludes that the blood sugar curves characteristic for certain tuberculous processes can be interpreted as an allergic phenomenon in children. This phenomenon manifests itself in a disturbance of the carbohydrate metabolism, particularly in the regulatory action of the liver. The existence of a functional disturbance of the liver was demonstrated by tolerance tests with levulose. The author gives a theory of the rôle of allergy in the development of the tuberculous process. He thinks, however, that studies on a larger material will be necessary in order to determine whether the course of the alimentary blood sugar curve can be used as an indicator for the type or the degree of activity of a tuberculous pulmonary process, or can serve as a diagnostic or a prognostic method.

Prognostic Significance of Black Vomit.—Melchior states that the significance of black vomit in surgical diseases was first stressed by Dienlaffoy, who made his observations in cases of gangrenous appendicitis and pointed out that black vomit indicated an unfavorable prognosis for these cases. Erosions of the gastric mucosa, caused by necroses, form the anatomic substrate of the black vomit. The vomiting is occasionally extremely severe and quantities of from 300 to 400 cc. are eliminated. In weakened persons such hemorrhages may terminate fatally by causing suffocation. There is a relationship between black vomit and hemorrhages that have been observed after abdominal operations, particularly after those complicated by infections, but in recent years they seem to have become rare. However, they do seem to play a rather important part in peritonitis. If in these conditions the vomit is black and if rather large quantities are eliminated, the prognosis is unfavorable. The black vomit that is eliminated either spontaneously or by means of the stomach tube shortly after extensive interventions on the stomach should not be confused with the symptom of black vomit the author has in mind, for the former is temporary and has a favorable prognosis. The author calls attention to conditions of general sepsis, in which black vomit is a symptom. Here the prognosis is likewise unfavorable, for of the patients the author has observed only two recovered. He thinks that the symptom of black vomit has not been given sufficient attention in recent years, as some textbooks on surgical complications fail to mention it. He admits that, the before mentioned acute suffocation being rare, black vomit is usually not itself the cause of death. The fatal outcome is generally the result of the underlying disease, of which the vomiting of black blood is only a partial manifestation. The treatment can only be symptomatic, consisting of emptying the stomach, eventually by means of transnasal drainage, oral administration of fluid and care of the circulation.

What Can We Learn from American Neurosurgeons? B. Schlesinger.—p. 970.

Comparison Between Results of Direct Staining and Loewenstein's Culture Method in Examination of Secretions and Tissues. E. Jubés.—p. 976.

Experiences with Löwenstein's Immunization Ointment.—Siegl and Drach point out that the first immunization experiments with Löwenstein's diphtheria ointment produced comparatively favorable results. In the following years, Löwenstein tried to improve his ointment in order to better the results. The authors tried several of the modifications of the original ointment, but on the basis of the observations made with these they conclude that the hopes to improve the

first results have not been realized, for the modified preparations produced poorer immunizatory effects than did the original one. The authors doubt the practical value of the method.

Comparative Investigations on Complement.—Wendlberger and Volavsek summarize their studies as follows: 1. The complement content of the blood of normal persons varies between 0.025 and 0.037 cc. 2. In some dermatoses the complement titer does not differ from the normal. 3. Patients with malaria, one patient with leukemia, one with psoriasis and several with syphilis showed noticeable deviations from the normal titer. 4. In gonorrheal arthritides the complement content is normal, and in this respect they differ greatly from the rheumatic arthritides. The authors will report later their studies on the cause of the fluctuations of the complement.

Constitutional and Pathologic Anatomy of Hematogenous Form of Pulmonary Tuberculosis. W. H. Stefkó.—p. 385.

*Best Therapy of Pleural Exudates in Artificial Pneumothorax. P. Starcke.—p. 401.

Therapy of Pleural Exudates in Artificial Pneumothorax.—Starcke shows that according to some statistics pleural exudates are frequent in pneumothorax therapy, for of two statistics that he mentions one gives an incidence of 50 per cent and the other one of 68 per cent. He differentiates between sterile and infected exudates. The sterile exudates are of a rather benign character. The author thinks that their comparatively high incidence is due to the fact that the many small exudates of short duration, which frequently develop in the interval between two fillings, are generally counted into this group. Since this type of exudate develops as a rule immediately following a filling of the pneumothorax, the pulmonary collapse is probably responsible. The author shows that the former belief that the sudden and excessive stretching of the pleura is the cause is no longer tenable. He states that in the majority of these cases conservative measures, such as rest in bed and small doses of acetylsalicylic acid, will bring the desired results. The resorption of larger exudates may be promoted by moist packs and cutaneous irritants. Puncture is necessary only if the formation of exudate is rapid. Many of these exudates may be avoided by making the single fillings smaller and the intervals between them shorter. The added precaution of warming the pneumothorax air is unnecessary. He shows that the factors causing temporary exudates may also lead to the formation of chronic ones. Conservative measures and a single puncture are not sufficient in these cases. The prolonged existence of exudate and a lack of careful observation involve the danger of serious complications. The pressure may become too great, which is especially dangerous in cases of strandlike adhesions between lung and thoracic wall. In the roentgenogram the shadow of the exudate covers large portions of the lung and thus makes roentgenologic control impossible. In order to avoid tearing of adhering strands with consequent injury of the lung, and eventually an empyema with mixed infection, it is absolutely necessary to measure the intrathoracic pressure frequently. The author deplors that this pressure control is too often neglected. In case of a considerable excess pressure, it is of course necessary to withdraw a large part of the exudate and to replace it by a corresponding amount of air. Control of intrathoracic pressure is necessary also in order to avoid low pressure. A subnormal pressure must be counteracted by refilling with air. The author sees the greatest danger of the chronic exudates in the possibility that the pleural cavity may become rigid as a result of thickening of the pleura by the connective tissue formed from the fibrin deposited by the exudate. If this is the case, the pneumothorax must be maintained permanently or the rigid cavity must be removed by surgical intervention. The latter procedure is usually more difficult than is ordinarily assumed, for it may become necessary to remove portions of the thickened parietal pleura. In discussing the infected pneumothorax exudates, the author differentiates between purely tuberculous infections and mixed infections. He thinks that conservative measures should be tried first and that operative interventions should be postponed until the disease process has

reached a stage of rest. He describes the development of exudates with mixed infections and shows how they are frequently induced and how they may be prevented. He states that it is difficult to give general rules for the treatment but describes certain measures, such as drainage and thoracoplasty, and when and how they should be employed.

Vaginal Total Extirpation in Intravenous Anesthesia with Aid of My Injection Apparatus and Arm Support. G. von Bud.—p. 1833.

Significance in Extra-Uterine Pregnancy of Reaction I of Anterior Lobe of Hypophysis.—Spitzer points out that in the pregnancy reaction of Aschheim-Zondek three degrees are differentiated: follicle maturation (I), hemorrhage into a more or less matured follicle (II), and luteinization (III). Pregnancy is indicated only when reactions II and III are demonstrable. Reaction I is not indicative of pregnancy, since an increased elimination of the follicle maturation hormone may be observed in other conditions. After discussing the significance of the Aschheim-Zondek reaction in extra-uterine pregnancy, the author points out that reaction I is a valuable diagnostic aid in cases of extra-uterine pregnancy in which the fetus has died, for it may still be positive from one and a half to two months after the death of the fetus. Since the diagnosis of abortion of a tubal pregnancy may present great difficulties, the biologic laboratory test may be the only reliable factor. The author relates the histories of three cases in which the follicle maturation reaction corroborated the assumption of death of an extra-uterine pregnancy. In view of the fact that the symptoms of the death of the fetus in a tubal pregnancy are frequently mistaken for those of inflammatory tumors of the adnexa, the author decided to study the outcome of the follicle maturation reaction in women with inflammatory changes in the adnexa. Five of thirty women gave a positive follicle maturation reaction, but, on repetition of the test, two of these five gave a negative one. From this observation the author concludes that biologic tests should always be repeated. He admits that the number of examined cases may not be large enough to permit a reliable estimate of the relations of the follicle maturation reaction to inflammations of the adnexa. However, the difference from the hormone production in tubal abortion is sufficiently great to make the reaction a valuable aid in the differential diagnosis. The author calls attention to the peculiar behavior of the rapid pregnancy reaction in rabbits. The rabbit test seems to be more suitable for the diagnosis of the retention of decidua tissues or of incomplete abortion than the mouse test. Consequently the author recommends that the mouse test as well as the rabbit test be made in doubtful cases of dead extra-uterine pregnancy.

Intravenous Continuous Drop Infusion in Sepsis.—Kerner states that in rather hopeless appearing cases of sepsis he obtained favorable results with intravenous continued drop infusion. He has employed it for a number of years in all septic processes in which the symptoms assume a threatening character from the beginning, and in puerperal sepsis without definite localization, particularly when chills develop. He administers either physiologic solution of sodium chloride or a solution of dextrose with an addition of a circulatory medication that is a compound of epinephrine, ephedrin, strophanthin and a blood pressure active extract of the posterior lobe of the hypophysis. He admits that in sepsis it is difficult to estimate the efficacy of a therapeutic method, since many factors enter into the process and since the organism itself plays the decisive part, but he thinks that his method of continuous drop infusion has been of beneficial influence.

Aschheim-Zondek Reaction in Extra-Uterine Pregnancy.—Kaplan points out that in cases of extra-uterine pregnancy in which the ovum has died early conservative treatment

is possible, provided there is a guaranty that the hemorrhage into the abdominal cavity will not be repeated. The risk of a hemorrhage is not eliminated until the embryo and the trophoblast have been destroyed. The trophoblast ceases functioning some time after the death of the embryo. If a method could be found that would disclose whether the trophoblast is active or inactive, it would be possible to determine when operative and when conservative treatment can be employed. In cases in which the trophoblast is active, treatment should be operative, because they involve the danger of internal hemorrhage; however, in cases in which the trophoblast has ceased its activity, conservative treatment can be tried. The author thought that the Aschheim-Zondek reaction might be helpful in determining the activity of the trophoblast, and he studied the relationship between the Aschheim-Zondek reaction and the activity of the trophoblast in twenty-one women with extra-uterine pregnancy. At first he tried to determine the activity of the trophoblast on the basis of its morphologic aspects. However, after he had studied the morphologic structure in cases of positive as well as negative Aschheim-Zondek reaction, he reached the conclusion that there is no parallelism between the morphologic activity of the trophoblast and the outcome of the Aschheim-Zondek reaction and that the function of the trophoblast and its morphologic structure do not harmonize. In the further course of his studies the author resorted to a different method. He implanted into infantile mice from 0.2 to 0.3 Gm. of chorionic or placental tissue, and after ninety-six or a hundred hours examined the ovaries of the animals for the hypophyseal hormone reaction, because active chorionic tissue contains hormones (follicle maturation hormone and luteinization hormone), while inactive tissue does not contain hormones and therefore cannot produce the characteristic reaction. The results of these implantation methods were compared with the outcome of the Aschheim-Zondek reaction in the urine. The author reports the results of these tests in eleven cases. He reaches the conclusion that the Aschheim-Zondek reaction cannot serve as an indicator of the activity or the inactivity of the trophoblast and that consequently it is unsuitable as a basis for the decision whether active or conservative treatment is advisable in extra-uterine pregnancy. The experiments are valuable also in connection with the question of the source of the luteinizing hormone, for Zondek believes that this hormone originates in the anterior hypophysis, while Philipp maintains that it is a product of pregnancy and is produced in the chorion and the placenta. After reviewing experiments carried out by Zondek, Philipp, Schockart, Siebke, Hofbauer and others, the author states that, without denying that the placenta produces luteinizing hormone, he believes that other glands, such as the anterior hypophysis and the pineal body and perhaps others, likewise produce the hormone during pregnancy. This would explain why luteinizing hormone is still present in the urine a long time after the removal of a hydatidiform mole or of a macerated fetus when a trophoblast is no longer present in the organism. It would also explain the lack of parallelism between the hormone content of placenta and urine.

THE TREATMENT OF PSYCHONEUROSES IN GENERAL PRACTICE

LAUREN H. SMITH, M.D.

PHILADELPHIA

The treatment of psychoneuroses in general practice should be viewed with a broad meaning. Besides the common psychoneuroses, I will include the use of psychotherapy in distressing physical diseases, or in cases of any sort in which there may be an emotional or mental problem, and with any individual who might consult us as physicians for advice on any personal problem involving mental and physical adjustment to life. Patients suffering from frank mental disease need definite psychotherapy and other medical therapy, but consideration of this phase of the field is not included here.

In the classification of the psychoneuroses, one finds general agreement on four central types or symptom complexes; namely, neurasthenia, hysteria, psychasthenia and psychoneurotic anxiety states. The last group includes anxiety hysteria and anxiety neurosis. The latter conditions are difficult to differentiate definitely and for the purpose of this paper such differentiations are unimportant.

ETIOLOGIC FACTORS

The psychoneuroses as clinical entities are ancient. In the time of Hippocrates the etiology of hysteria was considered to be the "wandering womb." In 1934 there are gynecologists and others still advocating hysterectomy as a cure. In later times Charcot advanced the idea that hysteria was due to "inherited taint." Binet, psychologically minded, believed that a patient with hysteria possessed a "double consciousness." Babinski, although an organicist, maintained that all hysterical signs and symptoms were produced by suggestion and that any conditions not removable by suggestion were organic and not functional. Bernheim held much the same view. Still later one finds the psychoneuroses being identified more clearly as to types. Janet presented elaborate psychologic theories as to the different clinical types of psychoneuroses, more descriptive in significance than explanatory as to etiology.

Freud explains the occurrence of psychoneuroses on the basis that mental processes in and of themselves may be etiologically significant. In hysteria, Freud considers that the physical symptoms and signs are the result of mental content, unacceptable to the individual,

formerly repressed into the unconscious mind, becoming converted into substitute disguised symbols of the unacceptable mental content. In the same manner, unacceptable desires and wishes may be the origin of the symptoms. The situation is somewhat similar in psychasthenia, wherein an innocuous idea becomes the substitute for the unacceptable mental content. The anxiety states result from immediate difficulties, in which there is a disproportion between sexual excitations and sexual satisfaction and the emotional outlet takes place in the anxiety attack.

Dejerine's important contributions present the view that the psychoneuroses are of mental origin, and he emphasizes the importance of emotional causes being mishandled by incorrect thinking and mental attitudes. Ross in England and Riggs in this country more recently have elaborated and correlated similar views with recent psychophysiologic theory. White points out the loosely organized, faulty synthesis of personality in the hysterical patients, who seem to be children mentally.

Other etiologic theories may be mentioned as containing some points of more or less interest, such as constitutional differences, somatic weakness, hypersensitiveness of the autonomic nervous system, foci of infection, and auto-intoxication. These are particularly important in connection with their frequency of association with a psychoneurosis, rather than being actually significant as definite causes of the condition. In an analysis of 239 cases of psychoneuroses, Strecker and Ebaugh point out certain significant statistics, as follows: predisposition from unfavorable home life, 70 per cent; from constitutional predisposition, 85 per cent; precipitating factors from sex disturbances, 22 per cent; from accidents, 13 per cent; from marital difficulties, 12 per cent; from financial difficulties, operation and deaths, 9 to 11 per cent. Physical examinations showed operations present in 23 per cent, focal infection and physical defects in 9 per cent. Mental examinations showed overconcern in 89 per cent, anxiety in 45 per cent and fears in 33 per cent.

Endocrine disturbance or alteration of function is now popular in etiologic speculation.

The very divergence in these etiologic possibilities goes to accentuate the etiologic nonspecificity. Gathering the discussion together, let me state that I have reviewed important dynamic, physical, psychogenic and environmental factors. The "constitutional differences" and somatic weaknesses are undoubtedly contributing conditions; the peculiarities of functional irregularities of the autonomic nervous system are active manifestations of an existing psychoneurotic condition but one cannot determine whether they may be cause or result. Foci of infection, toxicity, sudden physical or mental shock, and other stress and strain may definitely

act as precipitating factors. Any of these forces are all contributory. Each individual adapts himself to these contributing factors through the use of the mind. In addition to these factors it is known that there are active influences at work within the mind itself. Such influences may be conscious mental problems, which are ordinarily termed worry or anxiety; more often they may be definite mental conflicts deeply situated because of occurrence within the unconscious part of the mind.

The means one has in making adjustment to such external and internal factors is of course one's mind. Such factors, no matter of what origin, have an end effect on the mind and, in turn, the mind becomes the mirror showing the compensation it reaches in handling or adjusting to the sum total of the external and internal stress and strain. Therefore, the psychoneurotic patient really is an individual in faulty adjustment with one, another or all of these factors, within or without. Therefore it may be correct to say that a condition exists due to etiology from a mental standpoint, since the lack of adjustment is due to the lack of satisfactory handling of the life situations in which the mind finds itself. I do not mean that one has a mental disease, as that would be a total surrender or overpowering of the mental functions. With the psychoneuroses, there is a partial difficulty in adjustment, which involves only a partial decompensation of the mind or individual.

Because I would consider the psychoneuroses to be basically of functional origin, within the mind itself, in later discussion of treatment it will be only logical to state that psychotherapy, or treatment of the mind, and by use of the mind, is the therapy of paramount importance.

DIAGNOSTIC FEATURES

The clinical types mentioned before are separated by no hard and fast lines. A careful, exhaustive study of any psychoneurotic patient may elicit symptoms enough to allow classification in any one of the four groups. Usually there is enough preponderance of one type of reaction to allow proper classification. Even though the differences of the four types are largely theoretical there are practical differences, which are important from the standpoint of therapy. I believe the most important points as far as diagnosis of the case is concerned are, first, an accurate, complete knowledge of the type of symptoms; second, a clear understanding as to the background and development of the symptoms; third, some comprehension of the dynamic forces that are contained therein. Knowledge of this sort cannot be secured except by painstaking history taking, physical and mental examinations, and deep interest in the patient. Then can one really plan for the patient a treatment that will be specific.

In connection with direct diagnosis of each type, I shall briefly outline cardinal symptoms and signs later, under symptomatology and in the description of typical cases.

In connection with differential diagnosis, the difference between a psychosis and a psychoneurosis is naturally important but usually not difficult. It is often considered that they are of difference in degree only, and even though it is difficult in some cases to make a distinction, actually they are fundamentally far different. The psychoneurotic patient lives in and deals with reality. Although many of the symptoms do not have physical or structural origin, they are real experiences to this type of patient. On the other hand, the

psychotic patient lives in and deals with unreality. His difficulties come from fantasy, delusion and imagination.

A few confusing situations commonly found may be mentioned. A beginning dementia praecox may show marked signs of neurasthenia or hysteria. Dementia paralytica and psychosis due to arteriosclerosis, slowly developing involutional melancholia, and mild depression may simulate neurasthenia. Some frank psychoses may show marked psychasthenic phobias or compulsions. Anxiety states are often present in hyperthyroidism. But in all psychotic cases the more rapid changing course of the condition, the physical and neurologic changes, and the presence of frank delusions serve to identify a psychosis quickly.

Serious chronic physical disease such as tuberculosis and carcinoma may have a neurasthenic beginning, but careful physical examinations should establish the proper diagnosis. There are neurotic personality types, which the experienced physician recognizes. Positive recognition of these types will aid in preventing confusion, not only in differentiating between symptoms of organic or functional origin but in evaluating the significance of any symptoms of organic causation that may occur in such patients.

SYMPTOMATOLOGY

The classic symptoms of neurasthenia consist of fatigue, usually extreme on the slightest exertion, either mental or physical; marked weakness in all activities; lack of concentration in all mental activity; local sensory symptoms of any type or intensity from any system; a mood of pessimism, discouragement or dejection, sometimes accompanied by anxiety and fears. Headache, backache, insomnia, feelings of inferiority, marked self centering of attention, and peculiar sensations are common.

Mrs. G. presented a characteristic case. She was admitted to the Pennsylvania Hospital at the age of 37. Her complaints were extreme weakness and fatigue, nausea followed by intermittent spells of diarrhea, crying spells, headache, gradual loss of weight, and marked intermittent pains in the legs, abdomen and back of neck.

These weaknesses and digestive disturbances had been present six months when an appendectomy was done to relieve her, and the operation was followed by an increase in weakness, and dejection, and for the next year she was in bed approximately half the time, "resting" to rid herself of weakness. She developed increasing sensitiveness to all sensory stimuli and for four months before coming to the hospital had not left her bed except to use a toilet jar in her room. There were no physical difficulties found to explain any part of the condition. Detailed study brought out no physical factors of great importance except a constitutional hypersensitiveness. There was uncovered a history of lifelong excessive self attention, extreme idealism and ambition based on innate feelings of inferiority because of unattractiveness; these points were accentuated in her marriage to a successful professor and by the beauty and superior intelligence of a 10 year old daughter; her conflict in this situation was aggravated by a desire for more attention and emotional response from the husband. With clear discussion of these matters and a frank facing of the personal problems hitherto evaded, insight on her part was secured, and cooperation as to a definite treatment plan on a basis of scheduled activity in work, exercise, and mental occupation followed. It was a long course of six months and more to recovery, and readjustment in mental attitude was needed for a year or two more to bring the patient to a fixed level of recovery.

Hysteria is so varied in its forms that the types of reactions patients may show will only be outlined. It is

as episodic in its occurrence as neurasthenia is constant and continued. The most common motor and sensory episodic occurrences are paralyses, anesthetics, paresthesias, hyperesthesias, cataleptic or trancelike manifestations, tics, choreiform movements and aphonia. Spectacular symptoms are amnesia, somnambulism, double personality episodes, hysterical psychotic reactions and other disturbances of consciousness. Usually a case shows one type of reaction, with very little mixture with other symptoms. Later attacks may be entirely of a different character.

One woman, aged 20, had fainting spells whenever she was confronted with any test or responsibility in school, such as an examination; later when working in a store, on hearing some very depressing news, she collapsed, complaining of abdominal pain located over McBurney's point. Physical examination showed local tenderness and a left-sided hemianesthesia, but no other physical or laboratory observations were significant. She was followed in the outpatient clinic, and at the time of the death of her mother developed a complete amnesia. Recovery from each of her attacks always occurred automatically within forty-eight hours. She possessed a personality often found in many patients with hysteria, characterized by an extreme desire for affection, marked dramatic emotionalization of all situations in which she moved, and sharpness of sensitiveness to color, sound and all esthetic contacts.

The tendency to dissociation in the hysterical patient is extreme and allies this type of psychoneurosis to some degree to the unrealities of the psychotic group.

The main symptoms of psychasthenia are contained in obsessions, compulsions, phobias, anxiety and nervous tension. The patients are clearly conscious and have full insight into the illogical content of their mind but seem powerless to control its vagaries.

One woman, aged 21, was so constantly doubting the morality of every one about her that she could think of nothing else; if this disappeared she would develop a doubt as to whether the front door was closed or the water spigot turned off. There was no question that these obsessions and doubts had a sexual significance for her.

The substitution of an innocuous idea as expressing deeper unacceptable wishes or desires in the psychasthenic patient is similar in some particulars to the substitution of the physical symptom in the hysterical patient.

A man, aged 37, had to check and recheck everything he did for fear that it was not correct. Unfortunately he was an accountant, and one can imagine the extra work it made for him. In a fashion his compulsion acted as a sort of punishment and it is interesting to note that, when it subsided, fantasies of a sexual nature became active.

Other symptoms are common, such as hand washing, repeated touching of certain objects, and inability to use certain numbers or objects. Very common is the feeling of the psychasthenic patient that he must not allow himself to get into any situation or place from which there is no escape. Some night I am going to hand a questionnaire to all persons sitting in the aisle seats and on the back row of a theater. This condition is common enough to make me believe that a large percentage of people taking these seats of easy access and escape are persons who are greatly susceptible to psychasthenic reactions.

It is also interesting to note that in this group a personality characteristic found is a tendency to be extremely particular, exact and precise. The old association of miserliness, exactness and constipation is a vulgar, amusing example.

Anxiety states are often very similar, although the variety of minor symptoms may be manifold. Characteristic intense anxiety and extreme fear, definitely connected with one idea or another, is quite constant. This emotional tension is manifested in attacks with great cardiac, respiratory, vasomotor or gastro-intestinal disturbance. Phobias of crowds, open spaces, closed spaces or impending death are as common as in psychasthenia. The anxiety states are similar in character in some respects to an "acute" neurasthenia.

A man, aged 31, consulted a surgeon because of chronic flatulence, belching, indigestion and tachycardia. The surgeon recognized the emotional tension behind the symptoms and uncovered many panic and fear reactions as well. He referred the patient for psychotherapeutic treatment and in the first hour of consultation the patient discussed at great length his anxieties, difficulties, symptoms and any other material he chose to bring up. He returned in one week to the psychiatrist, remarking that he had never unburdened himself before, nor had he ever felt deeply reassured about himself before. He delightedly volunteered the information that he had been absolutely symptomless since the previous interview. The psychiatrist told him that he would not remain symptom free but that, even though the symptoms would return, they could gradually be understood and adjusted and finally eliminated after some continued treatment. Throughout several weeks' careful study of his entire life and emotional habits, childhood personality traits, and analysis of his present-day difficulties, he reached a more efficient basis on which he was able to work out better personal, family and environmental adjustments. The previous lack of emotional outlets no longer persisted and other origins of his anxiety state were exhausted, giving him a slow but good return to normal health.

CONSIDERATIONS REGARDING TREATMENT

The basic etiology of psychoneuroses has been discussed as of functional origin, in reference to possibility of effective treatment. The importance of a complete detailed knowledge of the entire organism, mental and physical, has been emphasized as necessary for proper diagnosis. The clinical syndromes have been briefly outlined in order that a common ground of understanding may be reached. I will now take up material regarding the possible approaches for treatment of the patient.

Treatment, being a very wide subject, will be taken up from the following aspects: (1) the ideal treatment of the frankly ill or "acute" psychoneurotic patient in practice or in the hospital; (2) the types of treatment in vogue or used by the specialist; (3) the uses of psychoanalysis; (4) the basis of treatment through psychotherapy to make most effective advances in the prevention of psychoneuroses and a discussion of significant associated material.

The first step in contact with the patient is the taking of a detailed history from the patient. This may not be necessarily formal in the beginning, for an informal consultation or two in which the patient tells his story and gives his view as he wishes may fix confidence and respect for the physician because of his evident interest and patience as a good listener. This history must include details concerning the entire life, childhood, adolescence, youth and onward. The gaps in the history may be even more significant than the material given. More is needed than physical illnesses and happenings. Facts about personality development, emotional experiences, points about the inner mental life and what influences there have been on it, and what habits or attitudes in emotional reactions thought and conduct ensued are very important. The attitude of the physician toward the patient is equally important, for, regardless of the social significance of the patient's

story or situation, the physician must remain entirely uncritical, at least at the beginning. All of the history in an ill patient will never come forth in the early interviews. It is a long job to correlate all one finds out from a patient, and a gradual construction of the origin, development and course of the illness must be made. As treatment progresses, one may be surprised to find new significant recollections uncovered in the history, even after months. The patient may not be evading or lying; it may have been impossible to recall or uncover these points before.

After an initial consultation or two regarding history, a complete physical study of the patient should be made. It cannot be emphasized too strongly that this should be done more conscientiously and with more care than when the patient has some simple physical disease, if such a difference in examining patients could exist. There are several reasons for this: First, the patient must be thoroughly examined by the physician in order that any physical factors may be properly evaluated as influences on the patient or as connected with the illness. Second, one must be certain that all treatment for physical disease may be adequately known and prescribed for, regardless of its connection or lack of connection with the psychoneurosis. To digress for a moment, the successful treatment of a psychoneurosis or any other type of disorder or disease depends on treating the individual as a unified mental and physical being, not as a being of separate mental and physical entities. Third, a complete physical study impresses the patient with the thoroughness of the physician, laying the basis for confidence in what the physician says. It would be very hard for the patient to accept the physician's statements and proof of the functional origin of the symptoms or difficulties if the patient considered that he had not been studied completely. There are exceptions to these points about physical examinations, but not in the general treatment of psychoneuroses, but only whenever specialized psychotherapy is given on theoretical grounds, and such exceptions lie outside the scope of this discussion.

By this time the physician has sufficient knowledge about his patient from history and examinations to make a definite plan for therapy. This plan is based on a careful study of the patient as an individual who reflects his environment and how it affects his reactions. The mental and physical aspects are studied and evaluated and are treated in proportion. A definite schedule of living should be drawn up on the proper balance of work, play, exercise and rest, according to the ability and need of the patient. The regularity, intensity and organization of an outline of psychotherapy for every aspect of the patient's mental life is the keynote of the treatment. What is psychotherapy? Psychotherapy may be termed any influence on a patient's thinking, feeling and acting that serves to produce a constructive, more efficient readjustment resulting in purposeful living. It is really organized planned mental realignment of the patient, arrived at largely through his own acquisition of insight and his own efforts.

His functional difficulties and symptoms must be worked out with the patient, as manifestations of his mental or emotional conflict. Carefully conducted reeducation, in an intelligent patient, will be successful in showing him how emotional disturbances have bodily effects and how anxiety attacks and fears likewise have deep seated origins within.

Whenever possible, readjustment of the external factors influencing the patient, such as relationship to

friends and relatives and to social, economic and financial matters, naturally is very necessary and is part of any complete treatment.

It is evident that treatment carried out along the lines just described is an involved and time taking procedure. In general practice such treatment may be impossible, for many practical reasons. For this reason, at the Institute of the Pennsylvania Hospital we are endeavoring to study methods of adequate psychotherapeutic treatment less involved. Some of these types of treatment may be applied in general practice, others may be best applied by the psychiatric specialist; but, planned as they may be, they do not approach as yet the ideal outline of treatment previously described. In time, however, we may be able to point out certain treatment principles, derived from study of these methods, that may help to evolve simplified but effectual plans of therapy.

In the clinics of the Institute of the Pennsylvania Hospital, the experience has been that patients divide more or less into about six "therapeutic" groups:

The first group consists of those patients who come for one interview, who merely want to get oriented as to the meaning of certain troublesome personality characteristics, intense mood swings or difficult behavior patterns. One may want to do little more than confess many difficulties and conflicts; another may wish reassurance and encouragement because of attitudes of inferiority; a third may be concerned over personal and family adjustments of the most difficult character. Evidently they seem to take pride in working things out for themselves, after getting a brief start in the correct direction. Perhaps it is better that the physician let them do so without further aid. Doubtless, many of them may be no better and may need to return but a trial on their own may prove very worth while.

A second large group is made up of patients who are not intelligent enough for careful self study and reeducation. Other factors too numerous to mention may prevent deep psychotherapy for a prolonged time. The medical practitioner must carry throughout life some individuals who need a physician as a sympathetic listener, a cautious adviser and friend who will dissuade them from too great anxiety by reassurance, suggestion, persuasion and finally through habit training, hydrotherapy, electrotherapy and various physical therapies. Little can be said in favor of a plan such as this, for it is usually employed because no plan can be made at all. This could be termed general psychotherapy, on the basis that the patient's problems are met squarely as of functional origin.

Reeducation is a form of psychotherapy very worth while, which is used in a third group. This group is made up of the more intelligent types of patients who realize to a certain extent the functional aspects of their problems. Such patients follow a plan that is closely allied to the ideal type of treatment described before. A special point made use of in this technic is the study and reading a patient does in connection with special written material on mental hygiene. The organized plan of study and discussion and balanced schedule of living that comprise much of this treatment appeal to the patient who is systematic. It is something very definite, which they can grasp and use. Any unconscious difficulties may be evaded or sublimated, however, and are undoubtedly little influenced.

With other patients it is sometimes necessary to dig deeper to find causes for their difficulties, and occasionally certain patients cannot face certain personal

problems until they are shown their possible deep-seated mental origins. Special technic such as the use of free association, word association, and the study of dreams may be used to get them to comprehend the mental and emotional aspects of their difficulties. This approach to the patient, dealing with methods that should be regarded as intensive psychotherapy, should be called deep psychotherapy as compared with a reeducational approach.

The fifth group is one in which there are comparatively few cases. In these are seen deep emotional conflicts or problems, which may not be influenced by deep psychotherapy. In order to uncover some of these problems, a modified psychoanalytic approach is utilized. By this I mean a purely psychoanalytic technic carried out once or twice a week, over a long period of time, to work out explanations and understanding of deep Modified psychoanalysis is no in the usual case, but in some instances this adaptation is of real help.

Orthodox psychoanalysis, the sixth and last group, is of limited application for a few cases. It has already contributed vast help to psychiatry as a whole and holds much promise for treatment for the more severe psychoneuroses. Before I proceed further, some discussion regarding it is in order.

THE CLINICAL RELATION AND IMPORTANCE OF PSYCHOANALYSIS

Besides the contributions psychoanalysis has made in other fields, much of the advance psychiatry and psychologic medicine has made in recent years is due to psychoanalytic contributions. By psychoanalysis I mean freudian orthodox psychoanalysis. It is a new psychology, a new understanding of the mental make-up of man, as well as a new technic in the treatment of nervous and mental patients. It cannot be denied justifiably that a great deal of the understanding now had of the deeper motivations underneath human emotional reactions and behavior has evolved largely from the psychoanalytic field. Before its advent, psychiatry was largely a descriptive diagnostic specialty in medicine. Now active psychiatric treatment is instituted in direct attack on symptoms and manifestations from the patient which are understood to a greater degree than ever before. This treatment is not by any means always psychoanalytic but a critical study of much psychiatric theory and practice shows it to have a foundation derived from what has been produced study. Nevertheless the views and who is almost solely responsible for psychoanalysis as it exists today, are not definitively and ultimately confirmed and proved. They are good helpful hypotheses. The use of psychoanalysis as a type of specialized treatment likewise is as yet not well enough established, and I am deeply conscious of its great limitations. My discussion at this point is not that of an enthusiastic psychoanalyst. It is the view of a physician practicing psychiatry as a specialty, in which is used orthodox psychoanalytic theory and technic.

The first requirements of good psychoanalytic treatment is that the psychiatrist have a fundamentally sound training culminating in his own analysis. The direct treatment with the patient is a formal interview involving an hour a day usually six days a week. The patient reclines, not facing the analyst, and is requested to utter his thoughts and express himself freely, with no reservations. His associations carry the study deeper and deeper, and childhood or deep memories,

fantasies, wishes, and so on, may be recalled and their emotional counterparts relived. The analyst more or less automatically becomes identified with the rôle of those individuals important in the life of the patient. The transference situation, or emotional tie-up between patient and analyst, is the outgrowth of this process. By guiding the patient in his associations and giving interpretations of the meaning of some of the recalled material, emotional responses, and also by similar study of accompanying dreams, the analyst is able to help the patient gain a better understanding of his deeper motivations. These processes have been buried in the unconscious part of his mind, and through this technic of treatment the deeply rooted origins of psychoneurotic symptoms and reaction patterns may be uncovered and relieved, and a cure established. The treatment is likewise used in personality difficulties and even in mental diseases, but with less success. As to its applicability, I believe that it will be most applicable and effective first with personality maladjustments, secondly with psychoneuroses of not too great a duration, and thirdly and most guardedly with some mild psychotic reactions. It must be remembered that psychoanalysis is essentially on one side a destructive process and, in the individuals with whom it is used, constructive possibilities must be present or the analyst must supply a substitute for such possibilities or damage instead of benefit may result.

There are many points in which the limitation of psychoanalysis appears. The patients ideally must have a good grade of intelligence; they must not be too old, preferably under 50 or 40; they must be willing to cooperate in this treatment; the resistance or normal defense reactions to deep analysis must not be too difficult to alter; there is a great amount of time and expense involved, owing to the frequency and length of treatment.

How much more effective psychoanalysis is in curing psychoneuroses than other forms of psychotherapy is yet to be proved. The psychoanalysts insist that all other forms of psychotherapy are superficial and only palliative and therefore futile. But many psychiatrists feel that other forms of general psychotherapy, using information gained from patients, and based on psychoanalytic theory, is effectual. Practically it is often obviously impossible to use psychoanalysis for several reasons, and other psychotherapy must be used in more possible lines.

THE GENERAL PRACTITIONER AND THE PRE- VENTION OF PSYCHONEUROSES

It is clear that the problem of treating the psychoneuroses in the community cannot be solved alone or best by effective treatment of the ill patient.

What is available to the general practitioner in the way of intensive psychotherapy? Little, in fact, little more than what he may intuitively possess or have acquired through years of active practice. He is definitely limited in treating the more severe psychoneuroses or problems of mental hygiene, mainly because he has never been given adequate opportunity in his earlier education and training. This condition is still true in most medical schools today. A second reason is that a busy general practice will not allow adequate treatment time to be given in an involved or advanced psychoneurosis. The psychiatrist must be called in to meet such problems as best he can. It follows then that the family physician must regard himself more as a potent influence in the field of prevention of nervous and mental disease, where he can be extremely effectual.

By expending much time and effort he may succeed with some, in fact with many, and be impressed with the fact that the solution of the huge number of functional nervous disorders is not in their actual treatment but in their prevention. In recent analysis of medical education in the United States, the National Committee for Mental Hygiene found adequate instruction in psychiatry for undergraduates in only ten out of sixty medical schools. Obviously the men graduating from these schools are going to practice medicine with an unbalanced approach toward the patient. This unbalanced approach may be one reason why the shady sisters of medicine, for example, chiropractic, Christian science, faith healing and similar charlatanry, flourishes so much today. And the economic difficulties which many of worth-while medical practitioners have besetting them today may be coming from the inroads made by these other so-called therapies. In one metropolitan area in the past year, 19 per cent of all the physicians had an income of less than \$1,000 a year. It is my honest belief that, if medical men in the community could and would use scientific consideration and therapy for the mental aspects of their patients' illnesses, these conditions would not exist as they exist today, and the better health due patients would likewise be assured.

The economic and social importance of the psychoneuroses is astounding. Conservative estimates have been made as to how many patients in general office practice have no physical or structural disease. These estimates run from 35 to 75 per cent. There is no question that there are hundreds of thousands of functional nervous disorders seen every day. The time these persons lose in health and happiness and in economic loss is appalling to consider. After these illnesses develop, treatment involves excessive study and time beyond that which the family physician can spare in a busy practice. The problem may be almost unsolvable as physicians try to meet it now. But in the development of the field of preventive medicine a technique of handling nervous patients may be built up in such a way that psychoneuroses do not take form. In infancy, childhood, puberty, adolescence, early youth, the menopause and old age, mental changes as well as physical changes take place. Treating the patient, whether physically or "nervously" ill, as an integrated individual in relation to his environment is of paramount importance. The individual is really an integrated whole, consisting of mental and physical aspects, each dependent on the other and influencing each other most profoundly. The effective prescription given for the best interests of the individual and patient should, in the ideal sense, contain therapeutic elements that will act as a specific for the mental side as well as for the physical.

In the last analysis, therefore, instead of considering the psychoneuroses as special conditions with which the psychiatrist deals, physicians should consider it basically a problem for general practice in preventive medicine.

SUMMARY

How can a psychoneurosis be prevented or aborted? Keeping in mind points already discussed regarding the make-up of patients and the factors that may be causative, let me list a few practical points as guides in handling an incipient psychoneurosis or psychoneurotic tendencies in any medical or surgical patient:

1. Recognition of the personality types that are likely to become maladjusted.

2. The recognition of specific emotional difficulties and their resulting symptoms. This means diagnosing a psychoneurosis from the finding of positive and specific psychoneurotic factors and symptoms, rather than merely making the diagnosis by exclusion because nothing else can be found to explain the condition.

3. Avoidance of comment before the patient about functional differences or changes in the organs that are not significant. This is extremely important with impressionable, emotional children.

4. Willingness to work out explanations and treatment for functional conditions bothering adults, instead of dismissing such difficulties on the basis of mere worry or imagination.

5. Specifying the direct purposes of all treatment and its relation to the patients' difficulty as a whole. Some patients tend to misinterpret the significance of treatment instituted and thereby their symptoms may become fixed or enhanced to a greater degree instead of being alleviated.

6. Direct, purposeful use of psychotherapy in all phases of medical practice, wherever there is any indication or possibility of such need.

There are a few great scientific men who are what they are because they are so scientific and need be nothing more. But no man can be a truly great physician who does not treat the mind of his physically ill patients as well as their physical illnesses.

Let the physician become more conscious of the fact that he is essentially a therapist. He should treat what the patient has got, not decide the patient has got what the specialist wants to treat.

The general practitioner is not only a chemotherapist and a physical therapist but likewise a psychotherapist. If he is really conscious of his constant psychotherapeutic influence with his patient he will carry further to absolute results the well being and improvement of his patient and raise the level of health and happiness in his community.

111 North Forty-Ninth Street.

ABSTRACT OF DISCUSSION

DR. ALAN D. FINLAYSON, Cleveland: Dr. Smith raised the question of whether a detailed history was not sometimes impossible. There is only one condition under which I can see that it is impossible, and that is when the patient visits the physician only once. Dr. Smith also made the statement that psychoanalysts claim that any other treatment, aside from psychoanalysis, is superficial and futile. With the term "superficial" I would agree. Most analysts, however, do not believe that other treatment is futile if an orthodox analysis cannot be done. Any treatment of the neurotic that is not based on the dynamic concept of their trouble is usually ineffectual. In a recent study by Dr. Ebaugh and his colleagues of medical education in the United States the statement was made that fifty out of the sixty medical colleges had inadequate instruction in psychiatry. I do not believe that the adequacy of a psychiatric course in college is dependent entirely on the number of hours given, but I do think it depends on whether it is presented from a dynamic standpoint. In other words, why does the patient act or think as he does? Why does he have hallucinations? I think that psychiatry is taught this way in comparatively few medical colleges. This lack of adequate psychiatric education is the answer to a great many difficulties the general physician has in handling the neurotic patient. In many chronic conditions, chronic disturbances of the heart, cancer, chronic kidney trouble, in which there is nothing that one can do to alleviate the condition, there is a great deal one can do in straightening out life's pathway and in making life far more comfortable for the patient.

DR. HAROLD S. COHN, Cleveland: I am interested in the treatment of neuroses only from the general practitioner's point of view. Dr. Smith in classifying the cases relative to treatment left out an enormous group whose neurotic symptoms are due to something that is usually ignored by the psychiatrist. That something is the economic factor. General practitioners see many patients with various types of neuroses and presenting a host of functional symptoms, particularly gastric. Invariably their trouble can be traced to the fact that they are worried financially. This is particularly true of the last four years. It is the economic factor in most of the ordinary neuroses. For this entire group Dr. Smith has not suggested any suitable remedy. It is this economic insecurity that causes most of the neuroses, and unless the neurologist or psychiatrist can tell how to solve this economic factor, general practitioners cannot treat such cases. The psychiatrist should be able to tell how to prescribe mental ease and freedom from worry as to economics. Another point is that as long as doctors who go into this field of medicine learn that the individual must adjust himself to his family, to himself and to society, they should learn something about the structure of society. I find that doctors do not know a thing about the economical and political structures of the society to which the individual has to adjust himself, and the doctor cannot adjust him to that society unless he knows that particular phase of it. In other words, training in the field of social science and economics should be added to the course of neurology in medical schools.

DR. LLOYD H. ZIEGLER, Albany, N. Y.: I am in accord with Dr. Finlayson that serious consideration should be given to doing away with the terms "neurasthenia" and "psychasthenia." If one will look into the historical aspects of the word "neurasthenia" one will find that it does have much basis, despite the fact that Baird used the term about the middle of the last century. It has been my experience that, if these so-called cases of neurasthenia are studied carefully, one may find Addison's disease, early parkinsonism, myasthenia gravis, psychotic developments, incipient pulmonary tuberculosis, and any one or more of a host of other possible diseases. The recent survey on psychiatric medical education made by the National Committee for Mental Hygiene discloses fundamental defects in the teaching of this subject in the majority of the medical schools today. Although much progress has been made in the teaching of psychiatry, most physicians in the past have been inadequately trained to deal with these difficult and intricate problems not usually explainable on somatic bases. There is no doubt that recent economic insecurities have affected the health of people variously. Some individuals with serious economic problems solve them with great equanimity. In others, trivial losses elicit outstanding maladaptations.

DR. T. EARL MOORE, Miami, Fla.: There are general practitioners, orthopedic men and cardiologists who are sending people to resorts to have "something" taken care of. What happens in the resort towns is that these patients come in contact with people who are psychiatric minded, the public as well as psychiatrists. It is the duty of the physicians in these resort towns to refer them back home. A vacation away from home is no panacea for psychiatric ills; as many founder as are helped by such treatment alone. The patient needs a psychiatrist back home much more than he needs a vacation. A correctly advised vacation, however, at the time indicated, may be specific therapy.

DR. LAUREN H. SMITH, Philadelphia: I agree with Dr. Finlayson that not all psychoanalysts consider other psychotherapy futile, although psychiatrists are more prone to consider other psychotherapeutic measures very worth while, even though they may be only palliative and not entirely curative. Dr. Moore mentions how the psychiatric patients are dumped on physicians at various summer resorts. This brings to mind how much better results are often obtained with the patient who is treated in a change of scene from home and relatives. Dr. Cohn has found his practice complicated because of the depression. In the consultation clinic we also found many cases in which the economic factor has been the precipitating and continuing cause of illness. With many patients, however, psychotherapy can be used to help them acquire a greater feeling of adequacy within themselves, particularly relating to the handling of the present economic problem, and they will

sometimes get along much better. Dr. Ziegler mentioned the matter of diagnosis. What may be an anxiety hysteria this week may soon be a full-blown obsessive psychasthenia, and at other times definitely neurasthenic in type. I do not feel that diagnoses are important if one gets at the fundamental dynamics back of the problem; and if the conditions are considered to be disturbances of the general integration of the individual the form of that manifestation does not matter so much if one knows the origin of it within. The relation of the problem to general medicine is of the utmost importance. Here at the convention two physicians, one a gastro-enterologist and one a specialist in arthritis, have told me their problems relating to neurotic tendencies in patients. The specialist in arthritis states that he is unable to do anything with a great percentage of his patients on a medical and dietary regimen unless he works with them over a long period on a purely psychotherapeutic basis. Likewise the gastro-enterologist said he considers himself about 50 per cent psychotherapist. A large number of patients are referred to the psychiatric clinic by the university gastro-enterologic clinic.

REDUCTION OF PREMATURE INFANT MORTALITY THROUGH DETERMINATION OF FETAL SIZE IN UTERO

AN ATTEMPT TO CONTROL WEIGHT AT BIRTH
ACCORDING TO THE COMPLICATION
OF PREGNANCY PRESENT

STEWART H. CLIFFORD, M.D.
BOSTON

During the past eleven years 30,781 infants weighing more than 5 pounds (2,268 Gm.) at birth have been delivered under the supervision of the Boston Lying-In Hospital with 378 neonatal deaths—a mortality of 1.2 per cent. In this same period there have been 958 infants delivered weighing less than 5 pounds with 364 deaths—a premature infant gross mortality of 38 per cent (chart 1). Thus it is seen that the premature infant group, representing but 3 per cent of the total births, contributes one half of the neonatal deaths. Ordinary pediatric methods have been unable to improve this situation, since over 80 per cent of the premature infant fatalities occurred within the first forty-eight hours following delivery (chart 2). Our experience during the past year suggests that the premature infant mortality can be reduced further by the simple method of delaying the induction of premature labor, whenever possible, until a viable baby can be assured.

It is a truism that the larger the premature infant the greater will be its chance of survival. Evidence has been obtained suggesting that the weekly gain in weight of the fetus in utero is 4 ounces (113 Gm.) during the seventh lunar month, 6 ounces (170 Gm.) during the eighth, and from 8 to 12 ounces (227 to 340 Gm.) per week during the ninth month. The close relationship that exists between the birth weight of the infant and its viability is demonstrated in chart 3—with each 8 ounce increment in body weight there is a striking reduction in the death rate. The importance of even one week's delay in the termination of pregnancy becomes apparent.

An analysis of 958 consecutive deliveries of premature infants reveals that the opportunity to control the

This is the fifth in a series of Studies on the Reduction of the New-Born Infant Death Rate from the Boston Lying-In Hospital, the Departments of Obstetrics and Pediatrics of the Harvard Medical School and the Department of Child Hygiene of the Harvard School of Public Health.

time at which pregnancy shall be terminated was present in 49 per cent of the cases. The mothers of 28 per cent of the premature infants had toxemia complicating their pregnancy, 7 per cent had vaginal bleeding of unknown cause, 5 per cent had placenta praevia, and 4 per cent had either diabetes mellitus, pyelitis or pulmonary disease.

Chart 1.—Total births and total deaths in the Boston Lying-In Hospital from 1923 to 1933.

delivery until viability is assured gives promise of effecting a material reduction of the premature infant mortality. The determination of the ideal moment for the elective termination of pregnancy in the individual case depends on the possession of reliable information concerning the size of the fetus in utero. A method whereby this knowledge can be obtained has recently been reported.¹ The occipitofrontal diameter of the fetal head in utero is measured by means of a modified roentgenometrie technic. The fundamental studies of Scammon and Calkins² have established that this diam-

Chart 2.—Percentage of premature infants dying at various ages.

eter serves as a reliable index as to the maturity of the fetus. As one is unaccustomed to think of the degree of fetal maturity in terms of occipitofrontal diameter, it has been necessary to translate this figure

into the understandable language of body weight. The relation that exists between the occipitofrontal diameter and the birth weight has been established through a study of more than 600 new-born infants. A graph has been prepared incorporating these data with the relation Scammon found to exist between this diameter and fetal age and with our statistics concerning the mortality for various weight groups (chart 4). It is possible, therefore, from a roentgen determination of the fetal head diameter in utero to predict the minimum and probable birth weight, the age of the fetus and the mortality to be expected. During the past year 240 such determinations have been made.

CONTROL OF THE BIRTH WEIGHT IN TOXEMIA

Pregnancies complicated by toxemia are responsible for a large proportion of the premature infants born alive and a still greater proportion of the premature infants stillborn. Toxemia apparently starves the fetus through involvement of the placenta and kills the fetus when the placenta becomes grossly infarcted or separates prematurely. It has been our experience that the

Chart 3.—Premature infant mortality according to birth weight.

infant of a toxemic mother is generally well developed but undernourished—it consistently approaches the minimum weight to be expected from its occipitofrontal diameter measurement rather than the average. It has also been our experience that, providing the toxemia does not kill the fetus in utero, premature infants of mothers with toxemia encounter the same mortality rate as do infants of comparable weight delivered of mothers with uncomplicated pregnancy³ (chart 5). The fetus in toxemia is exposed to two hazards—too early delivery and death from prematurity: too great a delay in delivery and a fatal intra-uterine accident.

Toxemia of pregnancy was present in 6 per cent of the 3,084 deliveries that took place in 1930. The fetus was stillborn in 12 per cent of the cases with this complication; one half of the stillborn infants weighed more than 5 pounds. The fetus was delivered alive as a premature infant in 11 per cent of the cases. In 10 per cent of the group the infant weighed from 5 to 6 pounds (2,268 to 2,722 Gm.) when delivered.

The possible relation between the level of the maternal blood pressure in toxemia and the occurrence of a

2. Scammon, R. E., and Calkins, L. A.: *Growth in the Fetal Period*, University of Minnesota Press, Minneapolis, 1929.

3. Clifford, S. H.: *Reduction of the Premature Infant Mortality: A New Approach Through the Estimation of Fetal Weight in Utero and as a Result of an Analysis of the Influence of Obstetrical Factors Upon the Viability of 958 Premature Infants*, J. Pediat. 5:139 (Aug.) 1934.

stillborn infant has been investigated in fifty-five cases to date. When the systolic pressure remained below 150 mm. of mercury, no stillborn infants were encountered. When the blood pressure was between 150 and 180, the stillbirth rate was 11 per cent. With the blood pressure between 180 and 210, the stillbirth rate was 43 per cent. As no pregnancy was allowed to continue to higher levels of blood pressure, there are no data available from this series as to the stillbirth rate for levels above 210.

In pregnancy complicated by toxemia in which the systolic blood pressure stays below 150, the evidence

Chart 4.—Relation of occipitofrontal diameter to birth weight, fetal age, mortality.

available at present indicates that there is little danger of intra-uterine death, and pregnancy might well be allowed to continue.

In pregnancy complicated by toxemia in which the systolic pressure remains between 150 and 180, the best interests of the fetus are served by a prolongation of pregnancy until a birth weight of 5 pounds can be assured and then delivery should be made. In toxemia of this degree the fetus is exposed to an 11 per cent chance of being stillborn. If the fetus were delivered weighing from 4 to 4½ pounds (1,814 to 2,040 Gm.) at birth it would encounter a 20 per cent mortality; from 5 to 6 pounds an expected mortality of 3 per cent, and above 6 pounds an expected mortality of 0.7 per cent.

In pregnancy complicated by toxemia in which the systolic pressure remains between 180 and 210, the fetus has a better chance of surviving if delivered as a 3½ pound (1,533 Gm.) or more premature infant than if pregnancy is prolonged in the hope of obtaining a larger baby. The stillbirth rate is 43 per cent in the presence of toxemia of this degree of severity, as opposed to a premature infant mortality rate of 32 per cent for infants weighing from 3½ to 4 pounds at birth.

The premature infant mortality statistics that have been given are based on a sufficiently large series to be significant. The relation between the blood pressure level in toxemia and the stillbirth rate that has been submitted is based on a study of fifty-five cases. The information concerning the fetus in toxemia is presented at this time in the nature of a preliminary report; much work remains to be done before this relationship is thoroughly understood.

CONTROL OF THE BIRTH WEIGHT IN HEART DISEASE

In pregnancy complicated by heart disease the fetus can be allowed to mature in utero with safety only as long as the mother presents no sign of cardiac failure. The fetal prognosis is better if pregnancy can be terminated prior to the onset of serious decompensation irrespective of the weight of the infant (chart 5). The premature infant mortality in the presence of congestive failure is 80 per cent; this is probably due to the fact that the majority of these infants must be delivered by cesarean section, that 73 per cent of the mothers have received morphine preceding delivery, and that the placental circulation must be involved in the general circulatory failure. It has been my impression that the prolongation of pregnancy in the presence of heart disease does not subject the fetus to the hazard of intra-uterine death, as is the case in toxemia.

CONTROL OF THE BIRTH WEIGHT IN THE PRESENCE OF BLEEDING

In the presence of gross vaginal bleeding, whether it is due to placenta praevia or to premature separation of the placenta, the sooner fetal delivery can be accomplished the better the infant's prognosis.

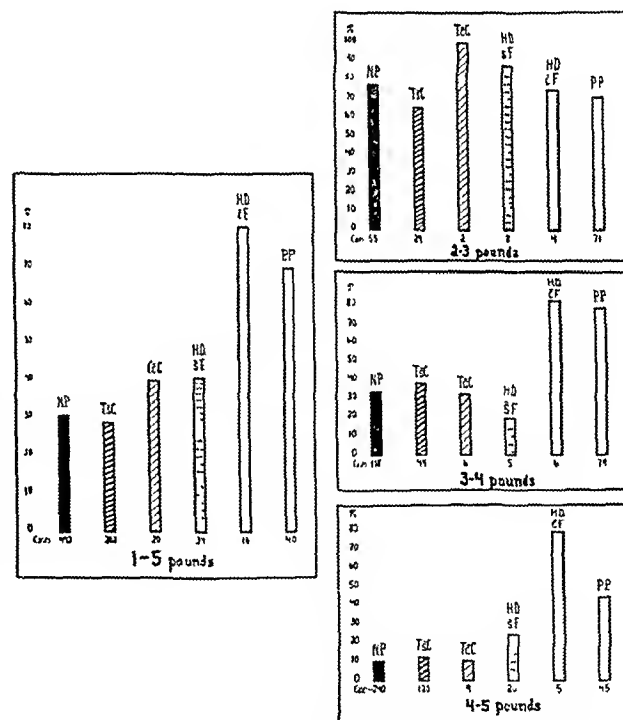

Chart 5.—Premature infant mortality according to complication of pregnancy by birth weight.

When the bleeding is slight and when the mother can be kept in a hospital under constant supervision, it may sometimes be possible to delay the gas examination and to determine the cause of the bleeding until such time as a viable fetus can be demonstrated.

CONTROL OF THE BIRTH WEIGHT IN THE PRESENCE OF DIABETES MELLITUS, PYELITIS OR PULMONARY DISEASE

When pregnancy is complicated by severe diabetes mellitus, pyelitis or pulmonary disease, it may be advisable to induce labor without regard to the size of the fetus. In the milder cases the demonstration of a fetus

of adequate size may make further prolongation of pregnancy unnecessary.

SUMMARY AND RESULTS

Further reduction in the distressingly high premature infant mortality depends on reducing the number of deaths in the first forty-eight hours of life. The condition of the premature infant at birth may be improved

by delaying the induction of labor, whenever possible, until an infant of adequate birth weight can be assured. An estimation of the weight of the fetus in utero can be obtained through mensuration of the occipitofrontal diameter of the fetal head by means of a modified roentgenometric technic, which diameter in turn can be translated into terms of expected body weight.

Chart 6—Stillbirth rate per thousand deliveries (includes miscarriages and premature nonviable infants).

In the severer grades of toxemia the situation may arise wherein it is safer for the fetus to take its chance being delivered as a premature infant than to run the risk of being stillborn should pregnancy be allowed to continue. The risk to the fetus of being delivered as a premature infant can be determined from information as to its expected birth weight. In reaching a decision this is compared with the chance of fetal death in utero as determined from an evaluation of the severity of the toxemia.

In pregnancy complicated by heart disease without failure there appears to be little danger of intra-uterine death of the fetus, and pregnancy may be allowed to continue as far as the maternal condition will permit. It is important to the future of the fetus that delivery should not be delayed until congestive failure develops, for under these circumstances the premature infant mortality mounts to 80 per cent.

Chart 7—Incidence of premature infants alive at birth; rate per thousand deliveries.

In the presence of gross bleeding the sooner the fetus can be delivered the better its prognosis.

The influence of knowledge as to the weight of the fetus in utero in the management of certain types of pregnancy is felt to have contributed to the reduction in the stillbirth rate to 47 in 1933 from a level of 69 per thousand deliveries for the preceding ten years

(chart 6). It has been instrumental in increasing the incidence of premature infants born alive from an average of 27.6 for the preceding ten years to 34.7 per thousand deliveries for 1933 (chart 7). Furthermore, the proportion of premature infants weighing from 4 to 5 pounds at birth increased from an average of 52 per cent for the preceding ten years to 61 per cent during 1933 (chart 8). Finally, the premature infant mortality dropped for the first time in five years from 35 per cent to 29 per cent (chart 8).

Two important additional influences collaborated with the determination of fetal maturity in effecting the improvements recorded. The general use of pentobarbital and scopolamine analgesia during labor has resulted in a definite reduction in the incidence of operative deliveries.⁴ With the mother relieved of pain, labor was allowed to pursue its natural course through full dilatation of the cervix to normal delivery. Secondly,

Chart 8—Relation of distribution of weight groups to general mortality by years.

there has been a better understanding of the safest method of accomplishing the actual delivery of a premature infant in the presence of the various complications of pregnancy.³

CONCLUSION

The premature infant mortality and the stillbirth rate can be reduced through control of the time at which pregnancy shall be terminated.

270 Commonwealth Avenue.

ABSTRACT OF DISCUSSION

DR. FRED L. ADAIR, Chicago: Despite popular ideas that seventh month infants are more apt to survive than those born at eight months, it is well established that the more mature the fetus the better are its chances of survival. Weight, however, cannot always be taken as a criterion of maturity, though in general the statement is correct. It is not clear from the presentation of Dr. Clifford what other factors may have entered into the reduction of the mortality of these premature infants. The method of delivery has much to do with the death or survival of infants and especially of those which are premature

⁴ Irving, F. C.; Berman, Saul, and Nelson, H. B. The Barbiturates and Other Hypnotics in Labor, Surg., Gynec. & Obst. 58:1 (Jan) 1934

Each week adds to the maturity as well as to the weight and length of the fetus. It seems to me that the length of the fetus is, as a rule, a better index of its maturity than the weight. Scammon and Calkins have presented numerous formulas for estimating body weight from various measurements of the fetus. X-ray methods, so far as they deal with the measurement of distances from tube to plate and the stereoscopic shift, are mathematically accurate, and intervening points can be accurately determined. The difficulty is to locate the points on the fetal head that one desires to measure. This can be done with approximate accuracy from the occipitofrontal diameter and the body length, and approximate menstrual age can be deduced. I use the method described by Hodges. It seems to me that the figures given by the author for weight gain during the ninth month are somewhat high even for infants of normal mothers. Physicians cannot and should not attempt to classify, treat or determine the time to interrupt pregnancy on the basis of blood pressure alone. It is unlikely that the author intended to convey any such idea. I should like to have my view clearly understood that the continuation of a pregnancy in a woman with a toxemia does progressive and irreparable damage of greater or less degree to her tissues and organs, and the longer the pregnancy is allowed to continue the more serious is the damage. One has to evaluate the relative importance of fetal and maternal lives. The so-called toxemias are not all alike in their effects on the mother, the fetus or the placenta, and there should be an attempt to make some differentiation between these various disorders. I am of the opinion that one cannot ordinarily temporize safely in the presence of genital bleeding during pregnancy and that a diagnosis should be made. Too many maternal and associated fetal fatalities result from the failure to recognize promptly the cause of the frequent warning bleeding of placenta praevia and ablatio placenta. I agree with the author that premature infant mortality and the stillbirth rate can be reduced through control of the time of terminating pregnancy. I should, however, like to emphasize the fact that in general any induction of labor increases the hazard for the mother and the fetus.

DR. JULIUS H. HESS, Chicago: I am certain that Dr. Adair welcomes the pediatrician into the field of obstetrics. In his clinic the babies go into the pediatric service shortly after birth. I am certain that a much lower morbidity has resulted from such cooperation. There is no gainsaying the fact that every half pound or pound added to the birth weight of the premature infant advances its opportunity not only for life but for a reduced morbidity. As the means are at hand for preventing refrigeration of infants, a proper nursing corps and food that is believed the best for this type of infant, breast milk, it is necessary to go back of the arrival of the infant in the hospital or the home, or the transfer from the obstetric department to the premature infant station, in order to reduce mortality, and that is exactly what has been attempted here. In a group of 1,623 premature infants, 238 of a total of 489 deaths occurred in the first forty-eight hours after admission to the station. In obstetric hospitals in which only premature births delivered in their own wards are received, the forty-eight hour death percentage would be higher, as most of the very small ones born in homes do not live long enough to be brought to the hospital. I was interested in the question of the different types of delivery, as regards not only the death rate but the factors that might influence the death rate. In the 1,623 brought to the station from 1922 to Jan. 1, 1934, in whom there were 489 deaths with 386 autopsies, there were the following: Induced labor with cervical dilatation, occurred eighteen times with six deaths, or 33⅓ per cent. All six infants had intracranial hemorrhage. Precipitate labor took place sixty-three times, with twenty deaths, or 31.7 per cent. Sixteen of the twenty had intracranial hemorrhages. There were sixty-three sections, with nineteen deaths, or 31.6 per cent. Two died with intracranial hemorrhages. This was a rather surprisingly low number. There were twenty-six spontaneous breech deliveries, with six deaths, or 23 per cent. Four infants had intracranial hemorrhages. There were eleven cases of version and extraction with one death, or 9 per cent, and that infant had an intracranial hemorrhage. Of twenty-three breech extractions, two infants died, or 8.7 per cent, one with intracranial hemorrhage. I was surprised by these facts, because I had always felt that next to

forceps extraction the breech extraction offered the greatest danger so far as intracranial hemorrhage was concerned. Forceps, high or low, were applied in 135 cases. Undoubtedly 90 per cent of these were low forceps. Nine infants, or 6.6 per cent died, and four had intracranial hemorrhages.

DR. STEWART H. CLIFFORD, Boston: Although the subject of applying the knowledge of the size of the fetus to practical obstetrics is new, it has become quite complicated. It is impossible to cover in a fifteen-minute period all the aspects of this subject that have developed. Therefore, in this presentation I limited the discussion to the time at which pregnancy should ideally be terminated. In another presentation, to which Dr. Hess has referred, I attempted to analyze the influence of the various types of delivery and complications of pregnancy on the premature infant mortality. The details of the report can be obtained in the *Journal of Pediatrics* for August 1934. In connection with the premature infant mortality associated with the method of delivery, I found the surprising fact that cesarean section, which is ordinarily thought to be the method of choice, actually carried the highest mortality of 44 per cent; delivery by breech extraction was next. The safest method for the delivery of the premature baby was found to be associated with low forceps application and the use of a wide episiotomy. In this case the mortality rate was 11 per cent. I agree wholeheartedly with Dr. Adair in his attempt to emphasize the value of skeletal measurements as a reliable index of fetal maturity as opposed to birth weight. The birth weight is extremely unreliable as an index of fetal age. Some day I hope the body length or the occipitofrontal diameter will be just as significant to the practitioner in this respect as the baby's weight. However, at present if I say that the baby has an occipitofrontal diameter of 11.5 cm. or that it is 47 cm. long, this probably means nothing at all to the listener. On the other hand, if I say that the baby in utero probably weighs 5 pounds, or at least weighs a minimum of 4½ pounds, one can immediately visualize the infant and plan accordingly.

THE SURGICAL TREATMENT OF CARCINOMA OF THE BRONCHI AND LUNGS

WILLIAM FRANCIS RIENHOFF JR., M.D.

AND

EDWIN NASH BROYLES, M.D.

BALTIMORE

In the treatment of malignant tumors of the lung and bronchi the same fundamental principles should be observed that are followed in the management of such tumors elsewhere in the body; namely, the removal of the entire organ and involved lymph glands when that is possible. Whenever feasible, this policy has been carried out regarding other organs and structures, following the advance in surgical views and technic. Total ablation by almost standardized operative methods has been developed for the breast, rectum and thyroid. To mention only a few, and is today a recognized procedure the world over. Partial removal of a breast for carcinoma would today be an unheard of procedure; in the instance of the lung, because of its unique anatomic structure, to be referred to later, a removal of the entire organ rather than a portion of it seems to be still more a requisite demand. Another point is that, owing to its structure and function, the total removal of the lung for even a benign tumor may be required as a measure to

From the Surgical Clinic of the Johns Hopkins University School of Medicine and Hospital.

A preliminary report of the operative technic appeared in the Bulletin of the Johns Hopkins Hospital 53: 390-393 (Dec.) 1933.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

Because of lack of space this article is abbreviated in THE JOURNAL. The complete article appears in the authors' reprints.

save a life, a fact demonstrated by one of the cases herein reported.

In the past, supposedly insurmountable technical difficulties have played a major rôle in retarding the progress of surgical intervention with bronchial and pulmonary malignant tumors. As in the surgical treatment of malignant conditions elsewhere in the body, so it will probably be of those in the lungs; namely, that a number of operative procedures will be suggested, developed and modified over a period of years until finally fairly standard methods will be evolved and accepted by virtue of their outstanding merits, applicability and effectiveness in various types of cases and conditions, in the hands of different operators and over a prolonged period of trial. It is not possible at this early stage in the development of total pneumonectomy to anticipate all possible technical pitfalls and immediate as well as remote consequences that no doubt will not be wanting.

It would seem advantageous, therefore, to present from time to time for consideration and discussion the experiences gained by those interested in this branch of surgery, for the total removal of the entire lung bids fair to become eventually the operation of choice in the surgical treatment of malignant tumors of the bronchi

Fig. 1 (case 1).—Diagrammatic sketch of the left lung, showing tumor, an intrabronchial fibropapilloma, filling entire bronchial tree.

and lungs. The development of a rational, safe and thorough operative procedure is therefore of prime importance. It is with this idea in mind that we present for consideration the limited experiences of two successful instances of pneumonectomy. In this brief report of the two cases, attention is called alike to the preoperative preparation and the operative technic

employed, to the postoperative follow up stage of the respective patients and, finally, to the critical discussion. It is of course impossible in the space allotted for the presentation of this report to discuss in detail the development of the operative treatment of malignant lung tumors and the interesting experiences and views of those contributing to this field of surgery.

REPORT OF CASES

CASE 1.—D. Y., a white girl, aged 3 years, admitted to Harriet Lane Home, Johns Hopkins Hospital, June 19, 1933, had been perfectly well until April 24, when she became ill and vomited at frequent intervals during the day. The pulse was slightly accelerated, the temperature 100.6 F., the respiration rate from 38 to 40. Examination of the chest revealed pronounced dullness on percussion of the entire left side of the chest posteriorly, which extended forward to the anterior axillary line. This dullness was especially marked over the scapular region. Over this entire area of dullness there was marked bronchial breathing. The patient was asymptomatic; there was no cough, and within forty-eight hours her pulse, temperature, and respirations became normal. The physical manifestations in the chest persisted and, in addition, within the next few days the dullness had extended over the entire anterior portion. The rectal temperature for the following two weeks showed an elevation to 99 and 99.6 F. Aspiration of the chest

was performed three times, twice unsuccessfully, and at one time 0.5 cc. of a thin, turbid fluid was obtained which on bacteriologic examination showed a few short chain streptococci.

Roentgen examination revealed no fluid in the pleural cavity, but the entire left side of the chest was hazy.

The heart was normal, displaced only slightly to the left. The blood pressure was 110 systolic, 82 diastolic.

Bronchoscopic examination, done by Dr. Edwin N. Broyles, revealed a small, glistening, yellowish tumor mass, completely filling the left bronchus and protruding well into the trachea toward the right side. A biopsy was possible and a diagnosis of spindle cell fibrosarcoma was made. Iodized poppy-seed oil could not be forced into the left primary bronchus. (Figure 1 shows the location of the tumor.) Since after several attempts it became evident that the tumor could not be resected through the bronchoscope, the patient was operated on, July 24, at which time a total left pneumonectomy was performed. The operation was carried out as described under operative technic.

Her convalescence was entirely uneventful. The temperature and pulse were never elevated after operation. The child was up on the fourth day and about the ward; the wound healed by first intention, and there was never the slightest evidence of infection in the wound or chest at any time. After operation the child was at no time short of breath or cyanotic, nor did she cough. The pathologic examination of the specimen revealed that the tumor was an intrabronchial fibropapilloma, which had arisen in the periphery of the lung and grown centripetally along the smaller bronchi into the left primary bronchus and trachea. The entire bronchial tree was completely filled with a tumor mass, which was everywhere covered with bronchial mucous membrane (fig. 1).

The patient has since returned several times for examination, which shows both on percussion and on auscultation that the heart and mediastinum have been displaced not only to the left but also posteriorly; that undoubtedly there is a large lappet of lung which has passed through the anterior mediastinum, displacing the heart posterior and to the left, and also that the lung in all probability has passed through the posterior mediastinum. The injection of iodized oil h.s. demonstrated by roentgenograms (fig. 7) that the main bronchus has healed completely and that the right lung has been expanded by compensatory dilatation and has migrated into the left thoracic cavity anteriorly, and probably also posteriorly. The heart shows no abnormalities. The child is perfectly well at present, almost a year since the operation. (fig. 8). The chest shows no deformity whatever, and the excursion of the left diaphragm is almost as great as that of the right. The expansion on the two sides of the chest is practically equal and symmetrical.

CASE 2.—*History.*—H. M., a woman, aged 24, complained of a constantly increasing sensation of pain in the left lower part of the chest anteriorly at about the level of the fourth rib. She located the pain in the precordial region and felt as if it was deep seated, a throbbing type of pain not associated definitely with respiration or cough.

In the summer of 1932 there was hemoptysis estimated at about two cupfuls of fresh blood, which she could feel coming up from low down in the chest after hearing a soft bubbling noise. Three months later she again coughed up a few mouthfuls of blood, and for the last two months she had had several small hemoptyses. Five days before admission the patient coughed up about a cupful of thick, dark blood four times during the day. Since that time she had coughed up a little constantly. She had some pain on taking a deep breath and on moving, at about the level of the fourth rib, as pointed out by the patient herself.

Examination.—The physical examination was essentially negative. The lungs were perfectly clear and no râles were heard. A roentgenogram of the chest revealed nontuberculous infiltration at the bases of both lungs.

The laboratory tests were negative.

Bronehoscopic examination, made by Dr. Edwin N. Broyles, showed a tumor about 1 inch below the first branch in the left bronchus. It seemed to be a small polyp, but only the apex of the tumor could be seen through the bronchoscope. Attempts at removal resulted in considerable bleeding. Attempts to remove the tumor through the bronchoscope and by fulguration were found to be unsuccessful after numerous trials. High

voltage roentgen therapy was likewise unsuccessful. Following bronchoscopic examination there was a great deal more pain in the left anterior portion of the chest at about the level of the fourth rib. Pathologic diagnosis of the particles removed by biopsy at the time of the bronchoscopic examination was carcinoma. An injection of iodized oil was made on the left side and a typical block found at the beginning of the left lower primary bronchus, just distal to the ventral bronchus. The iodized oil welled back into a rectangular mass.

The patient was admitted to the hospital, October 25, and an artificial pneumothorax was begun. November 1 the lung was practically collapsed. November 3 a left pneumonectomy was performed according to the technic described.

Preoperative Preparation—Beginning two weeks prior to operation, the left lung was compressed by a gradually induced and finally complete artificial pneumothorax. The patient thereby became accustomed to breathing only with the non-collapsed lung and so established, before operation, a respiratory and circulatory equilibrium under altered intrathoracic pressure.

Operative Technic—Tribrom-ethanol, 90 mg per kilogram by rectum, thirty minutes before operation and nitrous oxide and oxygen as a supplementary anesthetic were administered. Intratracheal anesthesia was not resorted to. The patient, accustomed to breathing with one lung, did not seem to be affected by the opening of the chest. The inconvenience of inserting a tube in the trachea was thereby obviated and also

veins lie in front of the left primary bronchus, and individual ligation of these can safely and easily be accomplished in their anterior presentation.

Ligation of the vessels offered no difficulty in either of these two cases. The pulmonary artery running in front and rather on top of the left bronchus was isolated by blunt dissection and clamped just midway between the reflection of the pericardium and the primary division of the artery (fig 13). The proximal arterial stump was then ligated with oiled braided silk and the mouth of the vessel transfixed with medium waved silk. The superior and inferior pulmonary veins were then isolated in turn and also transfixed with medium waved silk.

In case 1, in which operation was done July 24, the left primary bronchus was cut across with the scalpel and the lung removed from the chest (fig 14). The cartilaginous rings of the bronchial stump were cut at various points in their circumference in order to do away with their springlike action, which normally tends to maintain the patency of the bronchus. The bronchus was closed with a continuous suture of number 1 plain catgut in the mucosa supported by interrupted medium silk sutures in the wall of the bronchus. In case 2 (fig 13), in which operation was done November 3, the technic was the same, but owing to the location of the tumor (fig 15) it was possible to cut across the first ventral or superior branch and then incise the primary descending bronchus diagonally. There was very little loss of blood during the operation. The pulse

Fig 2 (case 1, one week after operation)—Air in the apex of the left thoracic cavity and definite fluid level, slight scoliosis to the left side, increased size of the right thoracic cage in comparison to the left. Intercostal spaces on the right are larger than on the left.

Fig 3 (case 1, two weeks after operation)—Practically all the fluid absorbed from the left thoracic cavity and mediastinum being pulled over to the left. Fibrous bands may be seen forming fenestrated labyrinthine cavity on the left side. Scoliosis is somewhat more pronounced. Intercostal spaces are relatively very much reduced in comparison to the right side. The heart is in the transverse position and the diaphragm somewhat elevated.

Fig 4 (case 1, on discharge from the hospital)—The trachea is somewhat displaced to the left, the fibrous adhesions hilling the left thoracic cavity, and the heart and mediastinum are pushed over to the left side. The diaphragm is not quite as elevated as in figure 3. At this stage physical signs indicated that the right lung had already migrated into the left thoracic cage. It is to be noted here that the intercostal spaces on the left side more nearly approximate the right side than at any time previously. The diaphragm is also in a much more normal position. These changes suggest that as the left thoracic cage fills with expanding right lung, respiratory movements may tend to normal and approximate those of the normal respiratory excursion of the diaphragm and the thorax.

an almost unavoidable contamination of the trachea and bronchi with infectious matter.

The patient's position on the operating table was the semi-recumbent one, with the right side down. The trunk was rotated toward the right at an angle of about 45 degrees, the left arm being raised over the head, and the head of the table elevated to 45 degrees. In that way the best exposure of the anterolateral surface of the left side of the chest was obtained, little if any weight being thrown on the right side and the diaphragm being simultaneously relieved of the weight of the underlying viscera.

After the usual iodine application to the skin and draping of the operative field, an incision was made in the third intercostal space, parallel to the third and fourth ribs and extending from the costal cartilages to the anterior axillary line (fig. 9). The fibers of the pectoralis major were divided along their course, the internal intercostal muscles cut directly across (fig 10). The parietal pleura herniated up between the ribs as a result of the increased intrathoracic pressure (fig 11), and after its incision air escaped with a hissing sound. The third and fourth ribs were merely spread apart with a self-retaining retractor (fig 12). The anterior approach was chosen, because it gives a far better exposure of the hilus; the pulmonary artery and

rate and blood pressure remained unaltered. The operations caused practically no

shock to the patients and were not unusually prolonged, thirty minutes being required for the first and one and one-half hours for the second. The spread ribs were reapproximated with number 2 silver wire, and the pectoral muscles, subcutaneous tissue and skin were sewed up with interrupted fine silk sutures (fig. 16). In both cases the chest was closed without drainage.

Postoperative Course.—As the convalescence differed somewhat in the two cases, and as each one offered especial points of interest, they will be considered separately. In the child, the pulse, temperature and respirations were undisturbed after the operation. One week following operation, a diagnostic thoracentesis yielded serosanguineous fluid, the culture of which proved to be sterile. Series of roentgen examinations of the chest following operation revealed first a gradual accumulation of fluid and some air in the left thoracic cavity. When after

two weeks that had almost completely disappeared, the formation of many delicate bands of fibrinous and fibrous adhesions running from the mediastinum and pericardium to the left chest wall and forming a number of small pockets with different fluid levels would be observed (figs. 2, 3, and 4). The chest cavity seemed to be honeycombed with an organizing fibrinous mass containing multilocular spaces of a labyrinthine aspect. The diaphragm became more elevated and immobile and the

Fig. 7 (case 1).—Iodized oil injection made by Dr. E. N. Broyles, April 27, 1934, ten months after operation, showing stump of left primary bronchus completely healed. The patient regurgitated some iodized oil and swallowed it, so that a small bit entered the esophagus and stomach. The right bronchial tree is shown, and on close inspection it can be seen that the ventral as well as the dorsal branches of the right primary bronchus cross the midline well into the left thoracic space. This shows a great deal more plainly in the roentgenogram than it does here.

heart and mediastinum shifted constantly more to the left side. At this time the right thoracic space was definitely by measurement larger than the left and was expanding vigorously, thereby exaggerating the enlargement. The bands of fibrous tissue seemed gradually to contract, becoming shorter as the mediastinum moved toward the left chest wall. In the first postoperative month the respiratory movements of the left side were absent and those on the right side became increasingly more conspicuous. An asymmetry of the thorax had evidently also developed by this time. The left thoracic space was diminished in its anteroposterior and lateral diameters, the intercostal spaces were markedly narrowed, and a scoliosis developed toward the left side (figs. 3 and 4). From this time on until the patient's discharge, the right lung as the result of compensatory dilatation began to extend to the left side and fill up the empty space that remained. A lingula of lung was seen to extend across the anterior mediastinum in front of the pericardium, pushing the heart toward the left chest wall and then posteriorly, as the expanding anterior lappet of lung became larger. Finally it inserted itself more and more in front of the heart, so that at present the point of maximum impulse is approximately in the midaxillary line. The large anterior lappet can readily be seen in the roentgenograms of the lateral chest view (fig. 5). The recent injection of iodized oil also proved this extension of the right lung to the left thoracic cavity (fig. 7). Physical signs on percussion and auscultation are further corroborative not only of the presence of lung tissue anteriorly in the left side but also of having penetrated the posterior mediastinum, coming across between the spinal column and the heart, below the arch of the aorta. Simultaneously with the filling of the left thoracic space, the respiratory excursion of the thorax and to a less extent of the diaphragm has returned. The diaphragm does not descend as far on the left as on the right side, but the movement of the thorax is apparently equal on the two sides. The asymmetry present before the filling of the chest with the extending right lobe disappeared along with the scoliosis. No empty space exists at present in the left thoracic cavity (fig. 6).

The convalescence of the second patient has differed in some quite obvious ways. Following operation the pulse rate fluctuated somewhat in correspondence with an elevation of temperature, which is shown in figure 17. The changes in the roentgenograms were identical with those of the first case; i. e., the chest filled with fluid and was gradually absorbed in the course of from two to three weeks, presenting the same type of fibrous bands resulting in the formation of multilocular

spaces. The lateral view showing these spaces containing different fluid levels is shown in figure 18.

Frequent exploratory thoracenteses revealed a dark red fluid containing some red and white blood cells but no infection. Never more than from 50 to 100 cc. could be recovered at a time. During the third week the patient, when turning on the right side in the morning (she slept on her back), would cough up from 25 to 50 cc. of this fluid. This expectoration persisted until about a week before her discharge, seven weeks after operation. Since that time it has not recurred. Roentgenograms at that time showed a small amount of fluid in a pocket, evidently connected with the left bronchus. The injection of iodized oil, April 25, corroborated this observation (figs. 19 and 20). The remainder of the left thoracic cavity is nearly filled out, by the displacement of the heart and mediastinum to the left and the elevation of the diaphragm. The left thoracic cage, if not entirely obliterated, is narrowed in all diameters; the intercostal spaces are likewise diminished, and through the formation of fibrous adhesions a space occupying fenestrated labyrinth of connective tissue has been created. In successive roentgen studies the walled off pocket connected with the bronchus is becoming smaller and will evidently disappear with an early closing of the now minute opening. Repeated readings of the intrathoracic pressure have all been zero, as could be expected because of a communication with the bronchus. Physical signs suggest further that the right lung has extended over to the left side, especially in the anterior and superior portion of the left side of the chest, and is occupying that space evacuated by the shift in the mediastinum to the left. Thereby the volume of the right thoracic space has been increased and also the right lung, which fills it (fig. 21). This aspect is supported by the steady increase in vital capacity since opera-

Fig. 9.—Operative technic.

tion; i. e., from 1.7 to 2.4 liters. The normal for this patient is 3.2 liters. Unfortunately, enough iodized oil was not introduced at this time to determine this fact. It will be interesting to note whether a negative pressure develops in the left thoracic cavity simultaneously with the closure of the bronchus and if so whether, as is very likely, respiratory movements will return with the filling up with lung tissue of the left thoracic cavity.

This train of events was noted in case 1. Patient 2 had a perfect functional result (figs. 22 and 23). She is the picture

of a very active young married woman in excellent health. It is interesting to note in this case that in spite of numerous colds during the winter the patient did not develop an infection of the cavity in communication with the bronchus. This communication is probably quite small. The patient has not coughed at all except for two days following the injection of iodized oil,

Fig. 10.—Operative technic.

which was allowed to run down the pharynx and which became undoubtedly infected. Other than that, she has been without morbid symptoms of any kind since operation and has been very active.

COMMENT

Incidental to the development of an operative technic for the removal of the thoracic esophagus, extending over a period of the last five years, it soon became evident that compression of the lung by an artificial pneumothorax would serve two very valuable purposes; i. e., first the patients were able to adapt themselves to breathing with the noncollapsed lung and also adjust themselves to the altered conditions of intrathoracic pressure that would exist during and after the operation. Thus the shock attendant on opening the pleural cavity was negligible. The second purpose was to remove the lung mechanically as far as possible from the operative field so as to give the maximum exposure of the mediastinum with the minimum handling of the lung. The relative simplicity of removing a collapsed lung under these conditions was at once evident, and therefore artificial pneumothorax was employed as a part of the preoperative preparation at the first opportunity. Other advantages of the preoperative pneumothorax are that in all probability the blood and lymph flow is markedly reduced, and intrathoracic exposure is very much increased, as the collapsed lung occupies a surprisingly small amount of space. Thus the operative removal can be accomplished through a relatively small incision in the chest wall; again, the necessary handling of the lung is reduced to a minimum and the opportunity for massaging emboli from a malignant tumor is lessened. It is to be recalled that tumors of the lung grow quite frequently along the pulmonary veins as well as the lymphatics.

The approach to the hilus of the lung through an incision in the anterior thoracic wall was selected

because from the anatomic as well as the surgical standpoint it is the most rational and simplest route. The hilus of the lung is thus completely exposed, so that an anatomic dissection may be deliberately and carefully performed. Thus the pulmonary artery and veins may be independently and securely ligated. These vessels lying essentially ventral to the main or primary bronchi are dispensed with in the beginning of the operation, thus insuring against the loss of any considerable amount of blood, and undoubtedly decreasing the probability of air emboli by way of the pulmonary veins. A secondary but still an important consideration is the ligation of the pulmonary veins before the lung is handled, preventing, of course, the escape of carcinomatous emboli into the peripheral arterial circulation through the left auricle. An excellent exposure to the mediastinum may be obtained at the level of the third interspace anteriorly, which permits of a dissection of not only the lymph glands of the hilus but also those of the posterior mediastinum as well. (Two neuromas of the mediastinum on the right and left side have been removed recently, this approach being used with excellent exposure). The anterolateral incision in the third interspace, from the parasternal to the anterior axillary line, permits without even so much as fracturing or cutting a rib, by simple spreading of the incision, ample exposure from the diaphragm to the apex of the thoracic cavity. In this manner not only is time saved but the added procedure of resecting ribs and dividing muscles is done away with.

The closure of the bronchus was done in these cases in a simple way with as little damage to the tissues as possible. The left primary bronchus was cut completely

Fig. 11.—Operative technic.

across with a scalpel in the first case just distal to the bifurcation of the trachea. The spring-like action of the cartilaginous rings was done away with by cutting the ring at several points in its circumference. The mucosa was sutured with a continuous suture of number 1 plain catgut, while the wall of the bronchus was

sutured with interrupted silk sutures. The bronchial stump healed by first intention, as shown in figure 7. In the second case, the tumor being located just distal to the first ventral branch of the left primary bronchus (fig. 15), the incision was carried through the inferior portion of the first ventral branch and then across the descending primary bronchus, the idea being that the

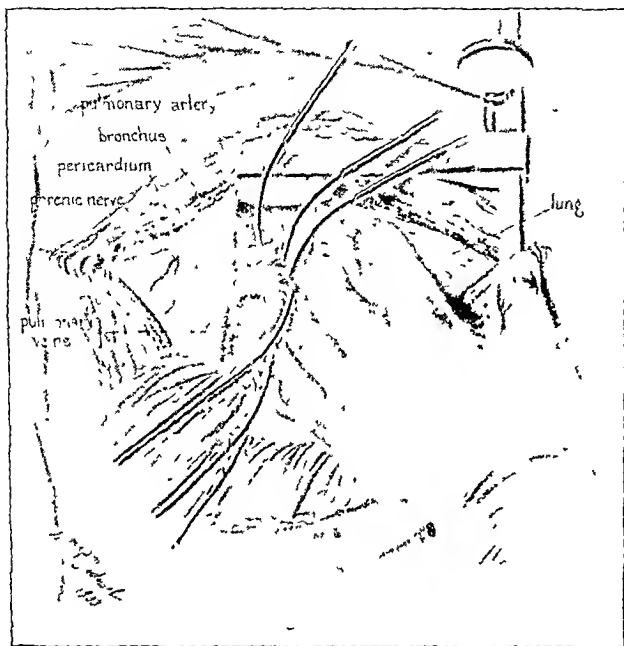

Fig. 12.—Operative technic

small first ventral branch might be closed independently of the large descending one and proceeding thus on the hypothesis that a small bronchus would more readily heal than a larger one. As a matter of fact the size of the large descending branch was very little reduced on the left side by the departure of the first ventral branch, remaining about the size of one's index finger and being equal in size to the bronchus in case 1. The result shown by the injection of iodized oil is almost self explanatory. The large bronchus healed by first intention while in the smaller one remained an opening the size of a thread. The same technic of closure was used in both cases. In the second case infection occurred prior to operation and was due to a bronchiectasis distal to the tumor and as a result of fulguration of the tumor through the bronchoscope.

Figure 20 demonstrates the walling off, pocket forming process about the end of the bronchus, which has been described. These results at least suggest that the bronchus may be securely closed in the human being and, further, if a small opening should occur after some days or weeks, that a walling off process may take place which makes this opening into the bronchus inconsequential. A small bronchus should probably not be left attached to the primary bronchus, for the reason that the circulation in the bronchial artery to such a small bit of tissue is more than likely disturbed in the closing of the main bronchus. Cauterization of the bronchial stump in any form is apt to cause a slough and prevent primary healing, or it may become a nidus of infection and should therefore be abandoned. Mass ligatures or tourniquets about the hilus are also harmful in that the bronchial artery is blocked far proximal

to the point at which the bronchus is cut across, and thus the bronchus for some distance is deprived of its circulation. Healing is thus retarded, to say the least, if not entirely prevented. In cases in which the primary bronchus is invaded toward the trachea, as in the first case, it would be impossible to cut across the bronchus proximal to the growth if the hilus should be tied off in a mass ligature.

Thoracoplasty is certainly unnecessary in pneumonectomy. The first patient fortunately had the juvenile resilience to compensate completely for the loss of an entire lung. This case may be considered from every point of view the ideal result, which for an older person would be unobtainable or only approximately so, as in the second case. Nevertheless, the maintenance of the normal shape and rigidity of the thoracic cage is a most important factor in the compensatory restitution. It serves somewhat as a sheet anchor to which the heart and mediastinum are attached by fibrous bands, probably profoundly influencing the intrathoracic pressure relations by maintaining the patency of the chest cage. What could be more upsetting to the cardiorespiratory mechanism than a flail wall to one side of the thoracic cage that moved in a large excursion with each respiration? Surely the ultimate effect of such a fluttering chest wall must be eventually deleterious. A sterile small pneumothorax is harmless, yet even that condition will be rare, for the cavity remaining in the thorax after the maximum compensatory dilatation of the

Fig. 13.—Operative technic.

remaining lung will gradually obliterate itself by the formation of multiple fibrous bands creating a veritable fenestrated labyrinth of many small spaces. (In eight consecutive cases of one stage lobectomies for bronchiectasis, in the presence of infection, the same process of obliteration has been observed. In none of these has

a thoracoplasty been found necessary.) Likewise in such cases should interference with the function of the phrenic nerve be given up, for the piston action of the diaphragm and its effect on intrathoracic pressure is a valuable adjuvant in the compensatory restitutive mechanism.

As far as could be ascertained from clinical examination, roentgen examination and thoracentesis, the compensatory restitutive mechanism consisted of the following steps: The remaining thoracic cavity, after removal of the lung, gradually fills after a

Fig. 14 (case 1).—Method of closure of left primary bronchus.

Fig. 15 (case 2).—Diagrammatic sketch showing relative position of tumor.

period of from forty-eight to ninety-six hours with an effusion of bloody serum possibly mixed with some old blood, clotted and unclotted, from the operation. This semifluid or fluid medium in addition to the entrapped air approximately fills the chest cavity. The latter rises to the apex of the cavity. Displacement of the mediastinum is by this means prevented in the first few hours or even days following operation. If the fluid in the cavity is sterile or even mildly infected (i. e., ability to obtain a growth but not pus formation), organization begins immediately and fibrous tissue strands develop from the costophrenic sinus and pericardium from below up much like the "sealing off" process occurring after pneumothorax in cases of pulmonary tuberculosis. Strands of fibrous tissue can be seen running from the pericardium and mediastinum to the lateral thoracic wall. The bands divide the thoracic cavity into many small spaces, which are lacelike in appearance and form a veritable labyrinthine network. Different fluid levels can be seen in these spaces. Undoubtedly as these fibrous bands contract they have a tendency to immobilize the diaphragm in a high fixed position but also to limit any respiratory movements of the chest wall and to pull the entire mediastinum and heart to the affected side. This readily explains the retraction of the interspaces and the ribs themselves, thus narrowing not only the lateral but also the anteroposterior diameter of the chest. Following the mediastinum evacuating its central position, the volume of the right thoracic cage is by this much increased and a compensatory dilatation of the remaining lung occurs simultaneously. If the mechanism ceases at this point the vital capacity is increased but moderately, as in the second case; but if a negative pressure is developed in the affected thoracic cavity the remaining lung will undergo further compensatory dilatation and fill the remaining empty space in the operated side, as in case 1. With this filling the respiratory movements seem to return. Whether or not the remaining lung advances to fill the empty space left by the operation seems to depend entirely on the pressure conditions in the

remaining space; if negative, the remaining lung will expand and fill the remaining space; if positive, the remaining lung will not hyperexpand or advance.

In treating malignant disease of the bronchi and lungs it is to be recalled that the spread of the growth may be (a) along the bronchi by continued growth or by bronchial embolism, (b) into the pulmonary veins and then carried into the left heart and peripheral arterial system without passing through the lung capillary system, (c) by direct extension of the growth from one lobe to another as the result of an incomplete anatomic fissure, (d) by anterograde and retrograde invasion of the lymphatics along the bronchi, involving the intra-lobar and interlobar glands as well as those of the hilus, and if the fissure is incomplete involving the lymphatics of the adjoining lobe.

For these reasons it would seem likely that total pneumonectomy would be followed by a higher percentage of ultimate cures than partial pneumonectomy, while at the same time in many instances it would be technically less difficult.

CONCLUSION

The important points of the method of operation here discussed are:

1. The preliminary collapse of the affected lung.
2. The anterolateral incision and approach.
3. The isolation and separate ligation of the pulmonary vessels.

Fig. 16.—Operative technic.

4. The primary closing of the bronchus after the cartilaginous spring has been interrupted.
5. The primary closing of the chest wall without drainage.
6. The prevention of postoperative sloughing and formation of bronchial fistulas.

7. The avoidance of resection of ribs and especially of thoracoplasty with its consequences.

8. The prevention of shock.

9. The comparatively short duration of operation and early convalescence.

1201 North Calvert Street.

ABSTRACT OF DISCUSSION

DR. EVARTS A. GRAHAM, St. Louis: Primary carcinoma of the bronchus is an exceedingly important subject, because it constitutes approximately 10 per cent of all cancers. It is possible to diagnose nearly all cases at a relatively early stage if the possibility of the condition is kept in mind. Since there have really been no authenticated cases that have been cured by radiotherapy of any kind, the only satisfactory treatment at present is by surgery. Drs. Womack and Tuttle, however, at St. Louis, have been going over some sixty-eight cases of ours with the idea in view of attempting to find out by classification and by other methods whether possibly certain types of cases might be considered to be more amenable to radiotherapy than to operative treatment; this study has not been completed. I congratulate the authors on their success. I am not certain, however, that the method which they used

was a year ago last April on a physician. I performed a thoracoplasty on him also because of the reasons mentioned, and I removed the mediastinal glands. He is perfectly well at present and he has resumed the practice of medicine. There is a strong probability that he will never have a recurrence, because the carcinoma had not penetrated the bronchial cartilage and there was no involvement of the mediastinal glands. The revival of interest in one stage resections of a lobe or of the lung is due to a great extent to the work of Dr. Brunn. The operation of a single stage lobectomy had been practically abandoned in this country until he revived it a few years ago for bronchiectasis.

DR. E. F. BUTLER, Elmira, N. Y.: The authors touched on a relatively new field in surgery—total unilateral pneumonectomy for carcinoma of the lung. In 1923 Lilienthal made a plea for operative intervention in these cases. He could not report any cases from his own series but he called attention to five cases in which operation had been performed in Sauerbruch's clinic. In this country there have been twelve or more cases of bronchogenic carcinoma of the lung in which total unilateral pneumonectomy has been done by Rienhoff, Graham, Alexander, Churchill, Overholt and others. The operative mortality has been low. In times past the diagnosis of carcinoma of the lung was usually arrived at during the course of operation for lung abscess or at autopsy. Now,

Fig. 18 (case 2).—Lateral view of the left thoracic cavity, three weeks after operation, showing different fluid levels in multilocular spaces formed by the space occupying fenestrated labyrinths of connective tissue fibrous bands.

Fig. 19 (case 2).—Iodized oil injection, April 25, 1934, showing filling of dilated end of descending left primary bronchus. A threadlike stream of iodized oil can be seen coursing down over the mediastinal side of the cavity connected with the bronchus. The diminution in the thoracic cage on the left side is similar to that observed in case 1. This was taken with the patient sitting in the upright position. Silver wire sutures have begun to break up in small pieces.

Fig. 20 (case 2).—April 25, 1934, after injection of iodized oil, with patient in recumbent position. Demonstrates size of cavity connected with the small threadlike opening that has persisted since about three weeks after operation. This opening, it is believed, is diminishing constantly.

will prove to be the best. I am fearful that in many old and middle-aged subjects a serious kinking of the large vessels will occur by the deflection of the mediastinum sufficient to fill up the empty space unless a thoracoplasty is performed. I wonder too whether emphysema is not likely to occur in the overdistended lung. Again, I feel that the mediastinal glands should be removed and, finally, I think it is safer to provide an air-tight drainage to prevent the serious effects of a tension pneumothorax if the bronchial stump should happen to open, and also to allow egress for the large amount of fluid that always collects. Possibly, future experience will show that although a thoracoplasty may be desirable it can be safely postponed until some time after the removal of the lung. The method of anterior approach, to attack the hilus first, appeals to me as having advantages over the posterior approach in some cases. The uncertainty about whether the tumors were malignant in both of the cases is at this time not so important as it may seem to others, because at this stage of the application of surgery to carcinoma of the bronchus it is important to develop satisfactory methods of attack. The anterior approach seems to me to be an important contribution. My first total removal of the lung for a carcinoma in one stage

and surgeon, the diagnosis may be accurately determined during the initial study of the case. Womack, reporting from Graham's clinic, has shown that the location of the carcinoma in the lung has a distinct prognostic significance. The nearer the original focus lies to the periphery of the lung, the shorter is the life expectancy; the nearer this focus lies to the hilus, the longer is life expectancy. Pneumonectomy and lobectomy are not yet standardized operations. They are still in the evolutionary stage. As a guide in developing the technic of these operations, there is a wealth of precedent and tradition. Six years ago Brunn disregarded precedent and developed a one-stage lobectomy, which has already won a secure place among the accepted thoracic operations. Rienhoff has also shown a disregard of precedent in his operative approach to the pedicle of the lung and in his indifference to the remaining dead space within the pleural cavity. His results have been good. It must be borne in mind, however, that the factor of suppuration did not enter to any great degree into Rienhoff's cases. When suppuration or sepsis becomes an important factor, the presence of a large empty

pleural space might invite an overwhelming postoperative infection. Rienhoff's patients and others operated on by similar technic will be watched with interest to determine the ultimate behavior of the mediastinum and also to determine the ultimate effect on the patient of mediastinal displacement that must presumably occur. These cases may later require thoracoplasty to correct excessive mediastinal shift.

DR. CLYDE ALLEN, Detroit: This presentation represents another milestone in a difficult problem of thoracic surgery. The question of the preliminary pneumothorax I think is of great significance. The necessity of crowding down the lung before attempting to remove it is, I believe, of prime importance. The operation on the phrenic nerve is of importance in reducing the size of the thoracic cavity before a shift of the lung to the other side is allowed. That problem, however, will be worked out as more experience comes. The question of drainage seems to be of great importance. I feel that an air-tight, water-sealed drain is the most satisfactory way of handling this problem. Four years ago I operated on a woman for carcinoma of the lung, which was diagnosed by bronchoscopy previous to the operation. I felt that, in spite of the fact that the patient was 65 years of age and had a rather marked hypertension, an attempt should be made to remove this and it was done in a two-stage operation. That is, a lobectomy was done. That was in 1930. This patient is now 69. Clinically she is well, but two and one-half years after the operation, bronchoscopy disclosed a small nodule in the stump of the right bronchus. A piece of this was taken out and it was found to be carcinoma of the same type, and radium was implanted. Since that time bronchoscopy has been done every six months and radium has been employed. She has had a total of 480 milligram hours.

DR. WILLIAM F. RIENHOFF JR., Baltimore: Fortunately the patients are young, so that it will be possible to settle some of these points if we all live long enough to follow them. I asked to have Dr. Graham discuss the paper because of his very large experience. In regard to kinking of the great vessels, C. S. Levy in 1920 reported the cases in the literature of congenital absence of the lung, including one that had come to autopsy at the Johns Hopkins Hospital, and in no case were there any evidences of disability from kinking of the large vessels of the mediastinum, although one lung was entirely absent. In the event of displacement of the mediastinum the heart is displaced, but this displacement is associated with rotation and I am not certain that there would be a kinking of the vessels. But whether there was or was not a kinking of the aorta and vena cava, it seems that a thoracoplasty might be performed at a later date if and when necessary. I am observing these patients continuously, as one lives in Baltimore and the other just outside. The younger patient has intelligent parents and they watch her closely. Physiologically and clinically they are both perfectly normal. If, and when, they develop signs or symptoms of a deleterious influence due to displacement of the mediastinum, then is the time to consider a thoracoplastic operation, not before. Furthermore, the question of whether a thoracoplasty would correct a disability from compensatory dilatation of the remaining lung is also, I think, open to question. Another thing about the congenital absence of lung is that none of them had emphysema at the time of autopsy. Compensatory dilatation of the remaining lung that Heuer, Reichert and I found after experimental pneumonectomy on dogs is an entirely different entity from a pathologic emphysema. It was found that the elastic tissue was not interrupted in the remaining lung after pneumonectomy. I can see no reason for draining the operated side of the thoracic cavity if it is sterile; but if it is not sterile and there is pus formation, I think that in twenty-four hours or forty-eight hours one may consider air-tight drainage through the incision or, if necessary, through an additional stab wound. If the cavity isn't infected I believe that through the clotting of blood and the presence of a supernatant serosanguineous fluid organization will occur with the formation of fibrinous and fibrous bands, which will transform the chest from a unilocular to a multilocular space. It is likely that the formation of fibrous tissue bands will occur more rapidly if the chest is full of some medium, a fluid medium or a semifluid one, than if the cavity is emptied by drainage. It is my opinion, which

may be entirely wrong, that a drainage tube is a hazard and if it is left in long enough, over forty-eight hours, infection will occur along the tube in spite of all precautions. Dr. Graham mentioned the lymph glands of the mediastinum. I forgot to state that I think in both of our cases we had very good exposure of the mediastinum. It was very simple to remove the glands along the posterior surface of the bronchus and in the mediastinum by either the anterior or the posterior approach. I have not meant to depart too radically from surgical precedents, but I feel that if drainage can be avoided, certainly in the uninfected cases, it will be a help in restoring that side of the thoracic cavity to normal.

EXPERIMENTAL STUDIES IN VASCULAR REPAIR

O. JASON DIXON, M.D.
KANSAS CITY, MO.

As we arrive in this world an intricate physiologic interruption in the circulation takes place which separates us from the maternal blood stream and places us entirely on our own. The success of this remarkable and most interesting process in the beginning of a new life hinges on a normal physiologic reaction; namely, thrombosis and the rapid healing or closing of an injured blood channel. As we depart from this biologic battle the last physiologic change in our bodies after our heart has ceased to beat is the clotting of blood within our veins.

During the interval between these terminal events of life, most of the pathologic changes that take place in the body have either directly or indirectly some bearing on the problem of thrombosis and the subsequent repair of this vascular damage. The healing of all wounds, the constant battle with infections, as well as the development and growth of the body, and the actual maintenance of life is dependent on this normal physiologic reaction. Karsner¹ describes repair as a reaction of the fixed tissue to an injury and divides it into three more or less intermingled stages; i. e., granulation, organization and cicatrization. Throughout this process the vascular changes play an extremely important part in the reconstruction. Although thrombosis is an intimate part of this vascular repair, the healing process is completely independent for, as MacCallum² says, "even when a thrombus fills the vessel and becomes replaced by fibrous tissue, the endothelial cells take no part in the formation of that tissue but confine their growth to the production of a new lining membrane which will cover all the surface of the clot and extend into every crevice, so that the blood is kept from contact with the fibrin or the new fibrous tissue." Hertzler³ has said that thrombosis is the most important problem in surgery and the least understood. As thrombosis is the first change that occurs in the process of vascular injury, it becomes a very important step in vascular repair.

When a needle is inserted into a vein for the withdrawal of blood, a certain amount of damage is done to this vein wall. A hole is torn in this tubular blood-filled channel and certain pathologic disturbances take place that might be the forerunner of immediate and

serious complications. The muscular coats and the elastic tissue in the vein wall immediately draw the wounded edges of the vessel firmly together. The injury to the vein permits a loss of tissue juices that are rich in fibrinogen, and when this substance comes in contact with the escaping blood under normal conditions a firm clot quickly forms and the opening is tightly sealed. This clot not only covers the outer sur-

reparative processes of injured veins are similar throughout the body, yet there are certain mechanical, physiologic and anatomic differences in the sigmoid sinus that might produce different reactions to injury. On account of the structure of the sigmoid sinus, eddies are formed in the circulating stream and there is a regular interruption of blood flow by the changes in intrathoracic pressure. There is such a fine balance and rich anastomosis with the other intracranial venous sinuses that all these factors are conducive to the formation of a thrombus and a rerouting of this normal venous return by way of the other patent channels.

ETIOLOGIC FACTORS

Various factors enter into the repair and restoration of the normal function of the venous channel, such as the manner in which the vein is injured, the amount of destruction of the vein wall, whether it is infectious, traumatic or both, and the duration of the inflammation; the condition of the patient's blood also plays an important part in all tissue repair. These mechanically produced vascular changes are not identical with those caused by the bacterial destruction of tissues. They differ, as MacCallum has stated, because bacteria may persist after healing has begun, and this may continue to repeat the injury. Although endothelial cells may have extraordinary powers of assuming other forms and functions, it is in the repair of vascular injuries that they have such a high degree of specificity, and the chief function of these endothelial cells in later life is the formation of a new lining for blood vessels.

TYPES OF EXPERIMENTS

The first series of experiments were the ligation of veins in the dog, varying in size from the internal jugular to the inferior vena cava. When these vessels

Fig. 1—A, cross section of external jugular vein showing the firmly attached noninfected retrograde thrombus. B, the vein wall, the intima of which was everted, showing the characteristic thickening resulting from this trauma.

face of the wounded vessel but extends over the damaged inner coats, and its size and shape are in proportion to the amount of venous damage.

What nature attempts to do, usually with success, is to maintain the venous channel as a blood carrier with as little interruption as possible, block the escape of blood through the wound promptly and repair the defect in the shortest space of time. Almost immediately after this intravenous or mural clot has formed, a lining similar to that of the normal blood vessel is laid down over the surface of the clot. I have been able to identify normal vascular endothelium on these clots within eighteen hours after the initial injury.

Immediate and fixed approximation of the wounded edges of the vessel is the best method for prompt repair. However, this may be highly impractical in some instances because the location of the injured vessel may not lend itself to the favorable technic and, in addition, the suturing of the inflamed and diseased vessel may not always safely prevent the loss of blood.

Certain vessels such as the sigmoid sinus are not amenable to ligation and suture repair. In the field of otolaryngology, this vessel is frequently infected and presents many perplexing problems. It is to the sigmoid sinus that the major portion of these experiments have been directed, although it has been necessary to resort to other venous channels in animal experiments. The sigmoid sinus offers many advantages for the study of thrombosis and vascular repair. It is easily exposed and this exposure can be maintained for a considerable length of time because it is not disturbed by the inflammatory reactions of the surrounding soft tissues. As it passes through the firm layers of the dura, this helps to keep the vessel open. While thrombosis and the

Fig. 2.—Nonviable muscle implant seven days after insertion, showing degenerated muscle fibers and organized thrombus.

were tightly ligated an intravenous thrombus formed at the site of the ligation, which was eventually absorbed; and although there was a compensatory hypertrophy of the collateral circulation to carry on a sufficient venous return, in no instance did the vessel recanalize past the point of obstruction.

In the next series of animals, nonviable muscle was used as a venous plug for the control of bleeding. This

nonviable tissue had many disadvantages. First, there was a tendency for it to slip out of the vein and permit a hemorrhage, either immediately after its insertion or from thirty-six to forty-eight hours later. Infection was more frequent and the reaction in the vein wall about the site of this nonviable tissue was always so great that the vein never recanalized (fig. 1). This reaction was apparently due to the necrosis of the non-

Fig. 3.—Vein with viable muscle loop placed intravenously sixty days before. The vein has completely recanalized along the opposite side of the viable muscle insertion.

used intravenously or extravenously for the repair of various types of vein wounds. The amount of the completeness of this venous repair by the use of viable muscle is extensive, and the unexpected results were startling. Briefly, these experiments were as follows: First, a viable strip of clean muscle was pushed into the open external jugular vein toward the head for a distance of from 2.5 to 5 cm. The muscle was held in place three minutes by narrow pointed thumb forceps. The venous flow had previously been obstructed beyond the point of opening by placing a hemostat on each side of the exposed vein and elevating the bed so as not to injure the vessel in any way. Care was also taken not to damage the vein at any point except at the site of the muscle entrance, the attempt being made to determine just what part the viable muscle played in the formation of the thrombus unaided by tissue juices from the damaged vessel wall. This muscle filled the opening into the vein but did not distend the venous channel. The valves toward the cardiac end of the vein blocked the venous return from this direction. This procedure controlled the bleeding and promoted the quick formation of a firm and well organized thrombus, which usually extended from 4 to 6 cm. up to the point of the first bifurcation. The muscle remained viable within the vessel, and within fourteen to twenty-one days a new venous channel was formed opposite the point of the viable muscle insertion and the vein returned to its normal size and shape. The viable muscle then became an extravenous implant as it remained enclosed within the old venous bed, the new channel being a detour which had formed around the muscle, and the vascular endothelium formed the new wall of the vessel, using the viable muscle as a base. The same venous repair and recanalization took place when two separate viable muscle implants were led into the vein in a cephalad direction. Because a longer strip of vein was blocked (fig. 3) it took a longer time for the recanalization to form, but again the vein was restored to its normal size. When an incision was made in the external jugular vein of the dog, viable muscle placed on this opening, and the edges of the muscle

sutured to the surrounding tissue, the escape of blood was completely blocked, and the venous channel was only partially occluded by the extravenous viable muscle. The opening into the vein healed so quickly that the injury could not be identified except at the site of attachment of the overlying muscle.

In another series the viable muscle was led into the vein and cut through an opening in the caudad end, and the raw ends of the extravenous muscle were sutured (fig. 4). In additional experiments, two strips of viable muscle were led into the vein from the caudad end and cephalad end and these raw ends were approximated intravenously (fig. 5), where they firmly united. In all these experiments, recanalization following the operative procedure always occurred.

When a segment of the vein wall was cut out over the intravenous strip of viable muscle (fig. 6), the defect was promptly repaired and the new channel formed in the usual manner. Finally, this vein overlying the intravenous loop of viable muscle was completely sectioned (fig. 7) and permitted to retract from 1 to 2 cm., leaving the bare muscle exposed, and again a new venous channel formed (fig. 8) over this muscular scaffold and both severed ends of the vein united so smoothly that it was impossible to determine the site of the previous injury (fig. 8). Aside from the fact that it took a longer period of time (from forty to ninety days) for this process to be completed, the reformation and reestablishment of this severed vein as a blood carrier was so complete that except for the remaining viable muscle loop it could not be differentiated on gross examination from the opposite vein, not

Fig. 4.—A, method of inserting a viable strip of muscle into the external jugular vein of the dog. The muscle is brought out of the vein at the point of exit of the needle. The exit and entrance are the only two places where the vein is traumatized, as it is not lifted from its bed. B, suturing of the raw muscle ends (C and N) after the viable muscle strip has been led through the vein. The muscle quickly united at this point of suture and did not undergo atrophy, because there is no loss of function.

operated on, that was used for a control. The part that the viable muscle plays in the reformation of an entirely new venous channel and the joining of these severed and separated venous ends is, in my mind, the most positive conclusive evidence of the part that viable muscle plays in venous repair.

Although it is difficult to understand and determine just how this large vessel can be so completely repaired, the entire process, although on a much larger scale, is not unlike the regeneration of the smaller blood vessels, which is comparable to the following description by Marchand:⁴

When such strands of endothelial cells, which at first may be no more than whiplash-like protoplasmic filaments, become united with others so as to form a bridge and become thickened

Fig. 5—Intravenous approximation of viable muscle ends. The raw muscle ends reunited firmly and a new venous channel formed alongside the viable muscle insert in the usual manner.

into a double row of cells by mitotic division, there gradually appears a cleft in the middle through which blood corpuscles are forced. There has been much discussion as to the part played by connective tissue cells in this process, but the evidence seems to be overwhelming in favor of the idea that when connective tissue cells take any part they act merely as supporting cells, applying themselves to the outside of the new tube, of which the essential lining layer is composed of endothelial cells alone.

Coffin⁵ made the same observation in the repair of lymphatic vessels. Obviously viable muscle acts in the same way as the connective tissue cells in that it merely serves as a supportive framework on which these newly developed vascular endothelial cells may easily and quickly regenerate. As the success of a tissue transplant depends primarily on the degree of specialization and the continuance of a constant and abundant blood supply, there are obviously two types of tissues well adapted to this experiment when viable muscle is used for vascular repair. It is well known that the failures resulting in the transplantation of the more highly specialized tissues are because the cells do not survive long enough to permit the development of new capillary blood vessels. Carrel⁶ emphasizes the importance of the maintenance of this vascular supply in his remarkable experiments such as the transplantation of the kidney.

Further proof that an injured vein may remain open during the process of repair is based on the experiment in the dog in which I made an incision into the inferior vena cava and closed the opening by the direct application of the raw surface of a strip of viable muscle taken from the anterior belly wall. No ligatures and no sutures were used as the blood stream was only temporarily occluded during the application by finger pressure, which was gradually released within five minutes after the muscle had been applied to the vein wound. The intestine was then allowed to fall back in place and the abdomen closed. In eleven of these operations there was no postoperative bleeding, including operations in two of the animals that developed a septic fatal peritonitis. Specimens of the vena cava taken at necropsy showed the mural thrombus covered with immature endothelial cells as early as eighteen hours after operation. In none of the animals was there any evidence of embolic disturbance, and never was a com-

plete occluding thrombus formed. The viable muscle strip undergoes the normal atrophy of disuse but remains fixed to the vena cava and does not produce distortion of the venous channel. Fibrin is thrown out so quickly about this raw muscle that it is necessary to dissect the finger free to prevent the removal of the muscle when the pressure is released from the vena cava. This also suggests that finger pressure should be carefully and slowly removed when the viable muscle is used to close the defect in the sigmoid sinus. The patency of the vena cava was confirmed by roentgen studies made after the injection of opaque mediums in the saphenous vein (fig. 9).

If complete occlusion of the sigmoid channel is desired after the infected thrombus has been removed, the viable muscle should be large enough to fill the vein completely and should be led into the sinus with a needle and thread and fixed in position. This method will produce a more extensive retrograde thrombosis and by detouring the circulating blood away from the infected vein should help to prevent a widespread dissemination of the infection. Regardless of whether the muscle is extravascular or intravascular or how far it is inserted into the venous channel, the experiments on the dog lead me to believe that eventually the obstructed sigmoid will recanalize and carry on its function as a blood carrier, provided its temporary obstruction is caused by viable muscle.

In this particular problem of the sigmoid sinus thrombosis the immediate operative complication,

Fig. 6—A segment (P M L) of vein wall removing the overlying intravenous viable muscle. This defect is repaired prior to the recanalization.

namely, the control of hemorrhage, has demanded and received the major amount of attention. While the control of hemorrhage is extremely important and quite necessary in immediately saving the life of the patient, it is by no means the only part of the problem. It is the infection within this blood channel that creates the destructive and often fatal complications, and surgical attention, if the surgeon's obligations are to be fulfilled, cannot be directed exclusively to the removal of the infected thrombus and the immediate control of hemorrhage. After this is done he has only exchanged this known infected thrombus for a new occluding thrombus which he hopes and trusts will not become reinfected. He can do more than hope and trust for these favorable results if he applies the patient's own tissue, that is, viable muscle, for the repair of this infectious and traumatic damage. He has removed only a part of the infection when he takes away the infected thrombus as he cannot, because of obvious anatomic reasons, remove the infected vein. Not only does this viable muscle produce less trauma to this injured vessel but it brings in some

additional blood and lymph supply, which may in some cases be enough to turn the tide for a favorable outcome. My experimental observations lead me to believe that the disadvantages in the use of this tissue are more theoretical than real, because in none of these animals have I encountered any embolic phenomena or any fatal postoperative hemorrhage when viable muscle is used. The application of viable muscle in the repair

of vascular injuries is by no means limited to the sigmoid sinus, but it is this particular phase of the problem that interests me in this specialized field of surgery, and I shall not report here the experiments that I have carried out successfully on the carotid arteries, liver, spleen, kidney and brain.

METHODS OF REPAIR

This viable muscle serves as a scaffold on which the new vascular endothelial tissue growth may take place,

Fig. 7.—Complete section and separation of the vein wall overlying the viable muscle implant. The viable muscle acts as a base on which the new vascular endothelium is laid down, and the defect is completely repaired and the vein recanalizes (see figure 8).

not only with more rapidity but in a definite fixed route, and as the scaffold is not removed the new vascular repair continues to rest on this supportive base. To a certain extent the direction of the formation of the new venous channel can be guided by this muscular scaffold. For instance, when a viable muscle loop is placed within a vein, the new channel always forms on the opposite side of the muscle implant. As the muscle remains viable in this transformed position it reinforces the damaged and weakened vascular wall even after the new venous channel has been completely reconstructed. It was this constant finding in the relation of venous repair to viable muscle implants that suggested the adaptability of viable muscle implants in the repair of certain types of aneurysms.

Reparative processes are carried on without apparent functional demands, as can well be demonstrated by some of these experiments. For instance, when the two external jugular veins in the dog are simultaneously blocked with viable muscle, a prompt and sufficient collateral venous return is established. This takes place by the dilatation of the subcutaneous veins and the compensatory dilatation of the smaller internal jugular veins. The compensation is so prompt and efficient that there is no clinical evidence of any circulatory block. Roentgen studies as well as postoperative exposure of the vessels at various intervals confirm these observations. With the ease by which this compensation is so fully and quickly developed it would seem that nature would be content to accept this new detour for the venous return, but she shows her resentment to this circulatory disturbance by always returning as far as possible to the old established channels. Almost immediately the dilated superficial veins again return to their normal size and the dilated internal jugular veins that were apparently carrying their extra burden without inconvenience quickly diminish to one third their newly acquired size.

OTHER TYPES OF EXPERIMENTS

After it had been definitely established that a new channel of normal size always formed along the opposite side of the viable muscle insert, various attempts were made to reroute this newly formed channel. For instance, the vein was sectioned below the insertion of the viable muscle to see if a new venous channel would

form out through the muscle. This never occurred. In order to determine what part the restoration of the venous channel plays in the recanalization of the vein beyond the viable muscle implant, I tied the vein with a silk ligature distal to the point of entrance of the viable muscle. As some authorities maintain that blood does not enter the newly formed capillary buds until these adjoining sprouts communicate and provide a circulation, it is quite interesting to note that in all the experiments a new channel was opened up past the muscle insert and to the point of the ligation exactly in the same manner as in those experiments in which the vein was not ligated. It was also proved that there was no venous return out through the viable muscle loop, as there was only normal bleeding when the muscle was cut, and microscopic sections showed only the normal vascular supply. It would appear from these experiments that nature repairs and restores the continuity of the venous channel up to the point of a permanent obstruction even without a functional demand.

CLINICAL APPLICATION

The clinical application of this problem to the human being consists of the following technic: After the sigmoid sinus has been exposed and the mastoidectomy completed, the mastoid incision is continued downward along the posterior border of the sternocleidomastoid muscle from 4 to 6 cm. (fig. 10 A). A strip of muscle which is left attached at the mastoid tip is separated and cut transversely at the lower border of the wound (fig. 10 B). This muscle should not be traumatized and should be left in the wound until ready for use. The sigmoid is then opened in the normal manner and the thrombus removed, preferably by suction. While the assistant occludes the upper and lower ends of the sigmoid to control bleeding, the viable muscle is either placed on the wound or led into the sinus with a needle and thread and fixed in position, as has been previously described; or the muscle may be held over the sigmoid wound by finger pressure for three or four minutes until enough fibrin firmly seals it and then petrolatum gauze packing is placed over this viable muscle explant to help hold it in position. Two different pathologic manifestations may indicate whether the muscle should be intravenous or extravascular. For instance, if the sigmoid sinus is accidentally opened or if it is opened and no thrombus is found, the extravascular muscle implant is preferable, because there is no advantage in completely occluding the venous stream and producing an extensive throm-

Fig. 8.—Specimen of external jugular vein with intravenous viable muscle implant that had had a complete section of the overlying vein wall one hundred days previously (see figure 7). The wounded vein borders are so smoothly united that evidence of previous injury could not be determined. The vein is restored to its normal size as a blood carrier.

bus. When a small opening is made in the sigmoid and viable muscle is laid on the wound to control the bleeding, I believe that only a mural thrombus forms at the site of the vein wound, which within a few hours is covered with vascular endothelium. Only while the muscle is being applied is the blood stream completely occluded. Further manipulations and disturbances to

I have not yet done in the human being, that viable muscle, i. e., sternocleidomastoid muscle, when used in the repair for either intentional or accidental injuries to the sigmoid sinus, is not only the best means available for the control of hemorrhage and promotion of healing but, when it is used, one may expect a recanalization and complete repair, the sigmoid sinus being restored to its normal function as a blood carrier.

ABSTRACT OF DISCUSSION

DR. MONT R. REID, Cincinnati: This paper illustrates the importance of a closer correlation and association between the various specialties of surgery. It too often happens that fundamental work remains cloistered for years in the field of the surgical specialty in which it originated. I am reminded of the life-saving procedure of ligating the jugular vein for septicemia resulting from a lateral sinus thrombosis. It is just beginning to find an application in the field of general surgery, where septicemias arising from infected foci in other parts of the body may be benefited by a similar procedure. I do hope that this excellent work of Dr. Dixon's will not suffer a similar fate but will reach the entire surgical profession quicker. He has drawn attention to the tremendous regenerative power possessed by the vascular endothelium provided it is given a chance to demonstrate this ability. Given a living vascularized tissue such as muscle, it will do it with amazing rapidity. In the absence of infection, it will do it quickly over free transplants of muscle which must secure their own blood supply

Fig. 9—Appearance after sublingual intravenous injection of diatriz of the external jugular veins sixty days following the insertion of gauze plugs, showing the compensatory collateral hypertrophy and failure to recanalize beyond the point of obstruction.

the vein wound are unnecessary and healing is in no way retarded. This method, I believe, is much to be preferred to the complete blocking of this channel with a foreign body such as a gauze plug, which is inserted through an infected wound and necessitates the formation of a complete occluding thrombus, which, being a nonviable tissue in direct communication with the circulating blood stream, is very apt to become infected and liberate bacteria directly into the circulation.

The use of viable muscle in vascular repair is based on a sound embryologic basis, as muscle and blood vessels both arise from the mesoderm. Also blood vessels contain within their coats muscle tissue, which is filled with blood vessels. In addition, blood vessels and muscle tissue are almost equally rich in the tissue juices that promote thrombosis. Apparently this muscle, which is used either intravenously or extravenously in the repair of venous wounds, is the most satisfactory tissue that could possibly be used for their repair. Not only does this raw viable muscle promote rapid and firm clotting but it hastens healing, helps to retard infection, minimizes the amount of trauma and, what is more remarkable, permits the severed vessel to restore itself as a normal blood carrier.

Based on these experimental observations I think it is fair to conclude even without necropsy studies, which

Fig. 10—A, lengthening of the normal mastoid incision over the sternocleidomastoid muscle in preparation of the muscle flap for insertion into the opened sigmoid. B, viable muscle applied to the defect in the sigmoid sinus that has been opened.

to live, in addition to furnishing a base, circulation and medium for the growth of endothelium. I speak of this because it has long been a practice among general surgeons to use plugs of muscle to control bleeding from veins or arteries when it is not possible or desirable to ligate the bleeding points. It is preferable to use adjacent and attached living muscle, but frequently, especially in brain surgery, this is not possible, and free transplants of muscle must be used. I am grateful to

Dr. Dixon for his demonstration of the probable ultimate fate of a vessel so treated. It is distinctly encouraging. It is well known that infection alters the process. When, however, the exigencies of the situation, such as his problem of the sigmoid sinus, demands a plugging of the wounded vessel, I am sure that his method of using attached, living and vascularized muscle is certainly the best procedure and a real contribution. In the practice of general surgery, one finds certain analogies in the use of pedicled muscular flaps for the obliteration of chronically infected empyema and bone cavities. Not only are the cavities obliterated, but the infection clears up more rapidly. It very likely will be proved that this use of pedicled muscle will not only be most beneficial in dealing with the open sigmoid sinus but will be a distinct benefit to the healing of the mastoid cavity. I should like to ask Dr. Dixon whether he would rely solely on the complete plugging of the sigmoid sinus with muscle when there exists a septicemia.

DR. LYMAN G. RICHARDS, Boston: This experimental work demonstrates conclusively that viable muscle tissue can be used effectively in the control of immediate venous bleeding. This is undoubtedly due, aside from the mechanical occlusion of the opening in the vein wall, to the thrombokinetic substances contained in the muscle tissue, a property that has long been made use of particularly by neurologic surgeons. Dr. Dixon's work brings out that the complete occlusion of the vein lumen by such viable muscle is followed by a complete recanalization of the vein, eliminating any objection to its use on this score. This is, therefore, a material of appropriate histologic and physiologic structure for use in the control of lateral sinus bleeding. Where such bleeding is the result of accidental trauma, the method of control here suggested would seem to be ideal. It avoids pressure packing and its consequent thrombosis and possible infection at the site of the compression. This method might well be reserved for those instances in which simpler measures fail. All are familiar with the ease with which a slight pressure with bone wax or gauze for a few minutes will at times seal over the tear with no further bleeding or compression packing. While the securing of the section of sternomastoid muscle is not complicated, it is one more additional procedure in the operative scheme. The greatest controversy will arise as to the use of the procedure in true septic phlebitis of thrombosis. Here the experimental work and the clinical situation diverge to a considerable extent, since in none of the experimental animals, as I understand this paper, was there any true septic venous thrombosis. Moreover, the external jugular vein of the dog has the advantage of easy mobilization and temporary occlusion from above, which does not exist in the case of the lateral sinus. Such ease of occlusion permits opening the vein and inserting a strip of muscle with much less interference from bleeding than has been my experience in mastoid surgery. It is true, of course, that the sinus can be compressed between the skull wall and the brain; but the resistance offered by the latter is not always such as to secure the complete obliteration that one would expect from certain pictures in the textbooks. Nevertheless, I have no doubt that muscle can be inserted into the sinus lumen after the removal, if present, of the septic clot.

DR. O. JASON DIXON, Kansas City, Mo.: In regard to the muscle becoming infected, it has long been known that muscle reacts very favorably in the presence of infection, and while I didn't report it here, I have carried on experiments with infection in the dog. I have also used viable muscle in man. I had a motion picture film here to show it, and also to show the amount of scar left. The only way I have been able to infect the thrombus in the dog is by the use of nasal discharge from a dog suffering from distemper. The dog is not susceptible to our virulent types of bacteria. I have injected streptococci from the brain of patients dying with otitic meningitis without the slightest reaction and when I use the usual discharge the dog develops a chill and runs the septic course of the human being. It is interesting to see how quickly that can be controlled, in some instances, by the removal of the focus of infection. Of course, any thrombus completely occludes the vessel. It is a question how extensive that thrombus is, how firm it is and how well organized. With muscle I find that the thrombus which forms is from six to eight times as extensive as when gauze is used. Therefore there is a better and

a more fixed plug and I also detour the circulating blood stream away from the point of infection farther back. Experimentally, in the human being one is dealing with an entirely different problem. Here there is a low pressure in the vein, bleeding is easily controlled, and, after all, one is dependent more or less on a pack and the overlying pack and the plug to control this bleeding. The particular advantage that I see is that it prevents the redisturbance of an infected wound. When the chills cease, and the patient is convalescing, I remove the gauze plug and start the process all over again. The muscle should be filled with petrolatum gauze, which acts as another safety pack. I am sure that if one ever tries it one will find it a very simple procedure to obtain the muscle. It shouldn't be traumatized, it shouldn't be handled with forceps, but aside from that one can do almost anything with it. One can get as much as one likes; there is always more than is needed, and I believe that it eventually will have some advantages. I believe that it is going to have certain advantages in other fields of surgery.

DISSECTING AORTIC ANEURYSM WRONGLY DIAGNOSED CORONARY THROMBOSIS

PAUL D. WHITE, M.D.
THEODORE L. BADGER, M.D.
AND
BENJAMIN CASTLEMAN, M.D.
BOSTON

The development of a dissecting aneurysm of the aorta may simulate closely acute coronary occlusion. We are presenting herewith an interesting and instructive case in which we ourselves were in error, with a discussion of the differential diagnosis.

Some ten years ago there spread through this country a sudden realization that coronary thrombosis with cardiac infarction was a common condition that could be diagnosed clinically. This was after more than a decade of surprising neglect of Herrick's¹ classic paper on the subject. Along with the dispersal of this knowledge there was then, as there has been since, much interest in the possibility of confusion of coronary thrombosis with some acute abdominal disease. Herrick himself and also quite early Levine and Tranter² called attention to this possible confusion. However, as a rule the distinction is an easy one to make if both conditions are borne in mind. The other common condition with which coronary thrombosis was in the past often confused is angina pectoris; the differentiation is, however, so clear that such a mistake is rarely made nowadays.

In recent years attention has been directed to two other conditions that can be much more difficult to distinguish clinically from coronary thrombosis than are acute abdominal disease and angina pectoris. These two conditions are extensive pulmonary embolism producing an acute cor pulmonale and dissecting aneurysm of the aorta. Both are serious. The former is the more common and hence the more important condition; it will form shortly the subject of a report by one of us (P. D. W.) with Dr. Sylvester McGinn. The latter is much rarer but also important because of its serious nature and of the likelihood of its being overlooked; it forms the subject of the present report. It is of

interest that among 7,000 necropsies at the Massachusetts General Hospital a dissecting aortic aneurysm has been found in eighteen and never correctly diagnosed before death (although thought of in two). In 50 per cent of these cases, death was caused by rupture of the aneurysm; in the others the aneurysms were merely incidental changes and did not produce any symptoms.

Fig. 1.—Electrocardiogram taken February 25, six hours after the onset of the severe pain. Leads 1, 2 and 3 are presented in sequence in this record and in the two to follow (figs. 2 and 3). The heavier time lines mark fifths of a second. Amplitude abscissas 10^{-4} volts.

REPORT OF CASE

History.—F. W. K., a man, aged 54, a lawyer, except for one attack of rheumatic fever in childhood had had no ill health until fifteen years before the present illness. At the age of 38, hypertension was discovered and slowly advanced to a recent level of 210 mm. of mercury systolic and 115 diastolic. The urine showed an increasing amount of albumin and of late a fixed low specific gravity of from 1.010 to 1.012

Fig. 2.—Electrocardiogram taken February 26, thirty hours after the onset of the pain.

with casts. Nocturia had developed, and some stiffness of the peripheral arteries was noted. During this period of medical observation covering fifteen years there were no cardiac symptoms or signs of failure except that three years before the present illness there was a mild attack of chest pain, thought by the attending physician to have been angina pectoris.

In 1920, twelve years before the present illness, carcinoma of the large bowel was discovered and resection was done, with the establishment of a permanent colostomy. In 1928 there were two important illnesses, pneumonia and appendi-

citis, for which appendectomy was done. The tonsils were removed in 1930.

During the three months just prior to the present illness the patient's vision had been failing and ophthalmoscopy showed retinal hemorrhages. Omitting tobacco helped his eyesight a good deal. Headaches during these months were relieved by acetylsalicylic acid. Routine examination early in January 1932, a few weeks before the present illness, revealed no serious abnormalities of the heart or lungs; the blood pressure at that time was 190 systolic and 100 diastolic. Soon after this the nonprotein nitrogen in the blood was found to be normal, 36 mg. per hundred cubic centimeters. The Wassermann reaction was negative.

The patient had worked hard for years with long hours and infrequent vacations. He smoked an average of twenty cigarettes a day for years and used alcohol and tea and coffee moderately. He exercised little.

The family history was unimportant except that his father had died of heart disease. Four children were alive and well.

Present Illness.—Feb. 25, 1932, eight days before death, he awoke in the morning at his usual time with a consciousness of a slight dull pain over the precordium, with no sense of constriction and no radiation. He dressed, breakfasted, and went to work as usual with the pain still present, uninfluenced by exertion, and showing very little detectable change. At about 11 a. m., while trying a case in court, he was suddenly seized by a severe constricting and penetrating pain over the

Fig. 3.—Electrocardiogram taken February 29, four days after the onset.

lower left side of the chest in front and extending somewhat into the right side of the chest. There was no radiation down either arm, but there was a sense of weakness and numbness in the left arm throughout. The pain extended laterally in the chest and grew steadily more severe and suffocating. He was forced to retire from the court room and to lie down for a few minutes. He then attempted to resume trial of his case but was unable to do so. It was at that time that a physician was called and found the patient complaining of excruciating pain in the left side of the chest. He was in profuse perspiration and collapse, lying on a couch. The color was pale and the eyes were apprehensive. The pupils were equal and regular and reacted to light and distance. The heart sounds were regular and of fair quality; no murmurs were heard. The pulse rate was 88 and the blood pressure 200 mm. of mercury systolic and 90 diastolic. The lungs were clear.

A tentative diagnosis of coronary thrombosis was made after inhalation of amyl nitrite had given no relief. Morphine sulphate was then injected subcutaneously in the dosage of one-fourth grain (0.016 Gm.) with very little relief. After fifteen minutes a second dose of one-fourth grain of morphine sulphate was injected. Gradually this afforded the patient definite relief but after another twenty minutes there was an accession of still more severe pain. A third dose of morphine sulphate (one-fourth grain) was then injected with very little relief. The patient was moved shortly after this by stretcher and ambulance to the hospital. The pain in the left side of the

The ascending aorta measured 7 cm. in circumference. It showed a moderate amount of arteriosclerosis. The arch

measured 6 cm. in circumference. It also showed a moderate amount of arteriosclerosis. In the outer portion of the media of the arch there was an organizing blood clot measuring 5.5 by 2.5 by 2.5 cm. This clot was moderately firm, slightly friable and grayish pink. It was adherent to both external and internal surfaces. There was a triangular ulceration with perforation of the intimal and medial coats of the arch, measuring approximately 8 by 5 mm. in extent, located at the junction of the arch with the left subclavian artery (figs. 5 and 6). There was a second triangular ulceration with perforation measuring 3 by 4 mm. in extent located in the central portion of the arch 2.5 cm. from the higher perforation. Both these perforations communicated with the blood clot in the dissecting aneurysm already described. The media was split almost completely in the thoracic portion of the descending aorta. There was an almost complete horizontal tear of the intima and media approximately 7 cm. below the arch. There was another but only partial horizontal tear 3.5 cm. below the arch. A portion of the blood clot dissected down the descending aorta as a narrow strip measuring 6 by 1 by 0.2 cm. At

Fig 6.—Detailed drawing showing the dissecting aneurysm of the descending thoracic aorta with the separation of its coats by the blood clot.

the terminal portion of the descending thoracic aorta just above the diaphragm there was a blood clot measuring approximately 7 by 3 by 1.5 cm. adherent to the external surface of the adventitia, the result of a perforation of the adventitial coat. This was the site of the origin of the blood found in the right pleural cavity. The aorta at the level of the sixth intercostal artery measured 5.6 cm. in circumference.

The abdominal aorta was moderately arteriosclerotic. There was partial splitting of the media, but no definite blood clot could be seen in the wall of the distal part of the abdominal aorta. In the portions that were not definitely separated, a thin purplish red line of apparent blood clot could be seen extending within the media down the descending aorta and also into the iliac arteries. The whole aortic wall was very friable and could easily be torn. This was more marked in the thoracic portion.

The pulmonary artery and venae cavae were normal.

The suprarenals were normal

The kidneys weighed 325 Gm. The capsules stripped with moderate ease, leaving a grayish surface that was studded

with small petechial reddish spots. The cortex measured 7 mm. in thickness. It was very pale and contained a few linear reddish areas and scattered yellowish glistening specks. There was a moderate amount of pelvic fat.

The heart's blood showed no growth on culture.

Microscopic Examination of the Aorta.—All sections showed a marked thickening of the wall. This was due in part to a marked fibrous and atheromatous thickening of the intima, but to a much larger extent to a dissecting clot of fibrin and red cells lying apparently in the outer third to quarter of the media and to marked proliferative and exudative changes in the adventitia. The inner layers of the media appeared essentially normal except in one or two areas where focal areas of scarring with loss of elastic tissue were noted. In the outer layer of the media, masses of red cells were noted dissecting their way between persistent elastic fibrils with an apparent destruction of the muscle cells. Several portions of the clot showed well marked early organization. The adventitia showed a very marked increase in the number of capillary vessels, which were often arranged in parallel rows at right angles to the lumen of the aorta. There was also a marked diffuse and focal polymorphonuclear and mononuclear infiltration in the immediate neighborhood of these proliferating capillaries.

FINAL ANATOMIC DIAGNOSES

The final anatomic diagnoses were as follows:

Dissecting aneurysm of the aorta (arch, descending thoracic, and abdominal) and of the iliac arteries.

Rupture of dissecting aneurysm of the aorta, descending thoracic.

Massive hemothorax, right.

Cardiac hypertrophy and dilatation, hypertensive type.

Acute endocarditis, mitral and aortic valves.

Arteriosclerosis; arteriolar sclerosis.

Chronic vascular nephritis, marked.

Pulmonary emphysema, slight.

Absence of rectum and sigmoid, old resection for carcinoma; colostomy.

Adenomatous polyps of colon and of cecum.

Papillary adenomas of the kidney.

Hyperplasia of prostate, slight.

Cysts of spleen, small, unclassified.

COMMENT

In this case the prolonged severe chest pain that we attributed to thrombosis of a good sized coronary artery resulting in a large myocardial infarct was without doubt due to the splitting of the coats of the aortic wall in the formation of the dissecting aneurysm. The beginning of the resolution of the blood clot in the aortic wall undoubtedly caused the fever and leukocytosis, which again we wrongly attributed to the resolution of a myocardial infarct. Finally, the sudden death due to the rupture of the aortic wall into the right pleural cavity after eight days of illness we considered at the time to be due to rupture of the heart wall itself, to the overwhelming effect of an attack of angina pectoris or to ventricular fibrillation.

An important symptom that may aid very much in at least suggesting dissecting aortic aneurysm, namely, pain in the back or referred to the back, was absent in our case. To be sure, the anterior chest pain did radiate laterally, but that happens with coronary thrombosis. Also the pain had a tearing character, but its suffocating quality was in keeping with coronary pain.

There were three clues of varying importance in our case that should have helped us more than they did. At the time we remarked about them and expressed surprise at their presence with such severe "coronary thrombosis." The first was the maintenance of hyper-

tension throughout, at first marked, later less. This we do not now recall to have encountered in any fatal case of coronary thrombosis. Of course any very severe pain may be attended by a state of "shock" with a sharp fall in blood pressure, but that was not the case in our patient unless it was very transient at the onset before the pressure could be obtained. This maintenance of high blood pressure was mentioned by Gager³ in a discussion of a case of dissecting aortic aneurysm in 1928.

The second clue in our case was the persistence of excellent heart action throughout. The heart sounds remained forceful with the aortic second much accentuated. No murmur or gallop rhythm developed at the apex, and there were no other signs of dilatation of the heart. Nor was there ever any suggestion of pericardial friction. The severity of the acute illness in our patient should have been attended or followed by some evidence of disturbed heart action had coronary thrombosis been to blame.

Finally, and most important of all, the electrocardiogram failed to show during the first five days after the onset of the very severe chest pain any indication of the important myocardial involvement that would necessarily have followed acute occlusion of a large coronary artery. We were much concerned at the time by this evidence, but we discounted it with the observation that here was a rare case of coronary thrombosis without "coronary T waves." We had never before encountered a case of proved severe myocardial infarction with practically normal electrocardiograms through the first week of the acute illness, nor have we in the two years that have elapsed since, but at the time we decided that this was an exception to the rule; we were wrong in that decision. Although coronary thrombosis chest leads have infrequently shown abnormalities in the electrocardiogram when the standard leads have not, we have ourselves as yet failed to find rapidly fatal myocardial infarction that did not give evidence of the condition in the standard leads at some time during the first week after the onset of the lesion. Undoubtedly chest leads (including the so-called lead 4) in this case would have been essentially normal; the patient came under our observation before we began to use routine chest leads in cases of suspected coronary thrombosis.

In 1921 Crowell⁴ summarized the literature on dissecting aortic aneurysms and reported four new cases. There were then on record about 275 cases. Death had occurred from rupture into the pericardial sac in 47 per cent of the cases. Kellogg and Heald⁵ in 1933 reported one of the last cases, and in their case the diagnosis was correctly made during life, on the basis of (a) sudden onset of pain which progressively spread, (b) evidence of interference of the arterial circulation to the lower part of the body⁶ and (c) the supportive family history of vascular disease and the past history of hypertension. Kellogg and Heald state that thirteen cases of dissecting aortic aneurysm are recorded in the

literature correctly diagnosed ante mortem.^{6a} Davy and Gates⁷ in 1922 reported an instance of dissecting aortic aneurysm in which sharp intense pain radiated straight back to the spine from the front of the chest, which one would expect to occur in more cases than actually happens. In their case sudden death on the nineteenth day was the result of rupture of the aneurysm into the left pleural cavity. In contrast to their case was one reported by Wedd and Thomas⁸ in 1931: A woman, aged 36, with marked essential hypertension (280 mm. of mercury systolic and 180 diastolic) for several months before death had no pain at all. In this case the lesion was unsuspected before autopsy; the final rupture into the pericardium was attended by blurring of vision, dizziness and syncope. Gager³ in 1928 in his case already referred to commented on the absence of coronary T waves in the electrocardiogram as well as on the maintenance of the hypertension during the acute illness.

Finally, a word is to be said about roentgen evidence. One may expect this to be generally disappointing, despite occasional clues. There are two chief reasons for failure of the x-rays to be of help in the majority of such cases. One of these is that the aorta is actually only slightly increased in size (circumference) in most cases by the hemorrhagic infiltration of its walls—this increase in caliber not being sufficient to make a notable prominence of the aorta, which tends to be somewhat enlarged anyway as a result of hypertension. The other reason is that only infrequently does one possess a control roentgenogram of the heart and aorta of the patient prior to the occurrence of the dissecting aneurysm.

SUMMARY

In a case of dissecting aneurysm of the aorta in a man, aged 54, we made a wrong diagnosis of coronary thrombosis because of the prolonged severe anterior chest pain at the onset, the fever and leukocytosis that followed, and the sudden death (from rupture of the aneurysm into the right pleural cavity), which occurred on the eighth day. Clues that should have helped us at least to question our diagnosis and to consider dissecting aortic aneurysm were (1) the maintenance of hypertension through the course of the acute illness. (2) the excellent heart action throughout, and, (3) most important of all, the absence of coronary T waves from the electrocardiograms of a severely ill patient during the first five days after the onset of the chest pain.⁹

6a. Since this paper was written there has appeared an important publication on dissecting aneurysms by T. Shennaw (Dissecting Aneurysms, Medical Research Council, Special Report Series, No. 193, London: His Majesty's Stationery Office, 1934). In this work the author has analyzed 300 cases with the involvement of the aorta in the great majority. Seventeen of the cases are from his own experience. Rare cases were diagnosed ante mortem.

7. Davy, H., and Gates, M.: Dissecting Aneurysm of Aorta, Brit. M. J. 1: 471 (March 25) 1922.

8. Wedd, A. M., and Thomas W. S.: Dissecting Aneurysm of the Aorta, Clifton M. Bull. 17: 154, 1931.

9. Within the past few weeks we have encountered a new case of dissecting aneurysm of the aorta which we diagnosed correctly during life, partly because of our experience with the case reported above but mainly because of two important points in the history, the first of which has not in some cases, we believe, been sufficiently recognized: (1) sudden overwhelming chest pain as if from the blow of a sledge hammer (in contrast to the more gradual development of the severe pain of coronary thrombosis) and (2) radiation of the pain, temporarily, toward the back and legs (not to the arms). This patient, a man of 57, developed slight fever (100 F. by mouth) and considerable leukocytosis (18,000) and died suddenly forty-eight hours after the onset of the pain. Postmortem examination showed a very extensive dissecting aneurysm involving the entire length of the aorta, penetrating even into the walls of both common iliac arteries and about the mouth of the right coronary artery (compression of which may have caused the slight abnormality that we found in the electrocardiogram—late inversion of T_a after a high origin, and flat T₂). In spite of the involvement of the common iliac arteries, there was not enough compression of them to prevent full pulsation in both dorsalis pedis arteries. Death resulted in this case from rupture of the dissecting aneurysm into the pericardium.

4. Crowell, P. D.: Dissecting Aneurysms of the Aorta: Report of Cases and Review of the Literature, J. A. M. A. 77: 2114 (Dec. 31) 1921.

5. Kellogg, Frederick, and Heald, A. H.: Dissecting Aneurysm of the Aorta: Report of Case Diagnosed During Life, J. A. M. A. 100: 1157 (April 15) 1933.

6. This is important evidence if present, but it is usually absent. It is due to the compression of the arterial branches, like the iliac, by the blood clot in the dissecting aortic wall. Even the coronary arteries may be so compressed, thus confusing still more the clinical picture.

THE EFFECTS OF CASTRATION IN THE ADULT MALE

E. P. McCULLAGH, M.D.

AND

J. F. RENSHAW, M.D.

CLEVELAND

In order to increase familiarity with the diagnostic evidence of hypogonadism in men, twelve post-pubertal castrates were subjected to careful clinical and laboratory studies, including bio-assays for the gonad-stimulating principles of the urine, and another substance from urine, presumably a testicular hormone which promotes comb growth in capons.

SYMPTOMS

Nervous and Vasomotor Symptoms.—The nervous and vasomotor symptoms of these castrated men constituted their most outstanding complaints. Unilateral castration did not give rise to any symptoms except a temporary diminution of libido in two cases. Complete castration, either by the simultaneous removal of both testes or by the removal of a single remaining gland, produced nervous and vasomotor disorders as early as the third day after operation. Nervousness was a major complaint of four patients at the time they were studied, although nine had experienced it at some time for varying periods after castration. The usual history was that the nervousness was first noted from three to eight weeks after operation. The patients' descriptions of this symptom were, for the most part, vague and poorly defined, but apparently there was a sensation of uncomfortable stimulation not unlike that resulting from a mild overdosage of thyroid. Such nervous excitability may be associated with a tendency to psychoneurosis, emotional instability and restlessness.

The vasomotor phenomena are closely allied with the nervousness and are usually the earliest symptoms of hypogonadism. Seven of these patients at the time they were examined complained of sudden flushing and sensations of heat or of chilling. Two of them had had such symptoms previously but had not noticed them for several years. The hot flashes occurred as many as four or five times daily for a period of several years and tended gradually to decrease in number and severity.

Potency.—Sexual potency (power of erection) and libido (sexual desire) were diminished in all twelve cases. Sexual impotence is not a distressing symptom in the absence of sexual desire. Hence, in the nine cases in which there was a complete loss of libido, neither partial nor complete impotence was a troublesome feature, but in the three cases in which there was a partial retention of libido, even partial impotence became a distressing symptom. Orgasms occurred in the cases in which potency was retained, but it is uncertain whether fluid was ejaculated. The knowledge that impotence exists and that it is disturbing normal domestic life has a tendency to be distressing, but psychoneurotic symptoms of any importance were present because of this in only one of these cases.

Psychic Symptoms.—Rowe¹ has stated that the "male castrate is subject to profound mental changes." This statement is not consistent with our observations. After the acute nervousness had subsided, our patients tended to display the quiet phlegmatic temperament

referred to by Barker.² In one there were obvious psychic abnormalities; but evidently these were associated with and caused by advanced generalized arteriosclerosis, for the abnormal psychic state preceded castration and was probably a factor in producing the patient's insistence that the operation be performed.

Muscular Symptoms.—It is an extremely difficult matter to evaluate the reduction of muscular strength in the human being. Judging from the statements of the patients, it appears that the sense of energy and endurance were decreased in ten cases, but whether or not there was a change in muscular strength as related to a single effort could not be determined accurately. In this connection, a study of two cases of eunuchism in which there were definite evidences of prepubertal hypogonadism is interesting. Both of the men were very intelligent. Long periods of systematic physical training failed to cause an important increase in the muscular strength or endurance of one man. A relatively long period of military training failed to increase the physical endurance of the second man to a degree comparable to that of the other men undergoing the same training. Neither of these patients had physical abnormalities except those associated with hypogonadism.

PHYSICAL SIGNS

Genitalia.—Of the physical features resulting from castration, those having to do with the genitalia, prostate and prostatic secretion deserve first consideration. Atrophy of the prostate was a constant and striking feature in all these cases except one in which prostatectomy had been performed prior to castration. The size of the prostate glands varied from one-half to one-fifth normal. In one case, Dr. W. E. Lower made the note that "this is the most complete prostatic atrophy I have ever seen." As further evidence of the atrophy, vigorous and repeated massage failed to produce any prostatic secretion in eight of the cases. In two instances, when secretion was obtained from the urethra it amounted to one or two drops and proved to be a thin, clear, milky-white fluid containing some lecithin bodies and an occasional leukocyte. No spermatozoa, granular prostatic cells or corpora amylacea were found.

Atrophy of the penis was less constant and less marked, and was recorded in only five cases. Even in these, the statement of the patient had to be accepted, since the organs could be considered to be within the limits of normal size. The seminal vesicles were not palpable in any of our cases.

Secondary Characteristics.—The pubic hair in all cases was scant and of the female type of distribution. The axillary, perineal and anal hair was very scant. The amount of body hair was definitely reduced in all but one case. The beard was less often affected. Five cases presented a slight hypotrichosis of the face. In one, the changes in the hair were questionable and six were not changed by castration. The scalp hair showed no consistent deviation from the normal.

Body Weight.—The weight of eight of the patients was increased within the first year after castration. Seven men showed abnormal accumulations of fat, chiefly about the abdomen and breasts. One man who had gained weight failed to show these features at the time of examination because of a subsequent progressive loss of weight caused by tuberculosis and syphilis.

From the Cleveland Clinic.

1. Rowe, A. W.: Studies of the Endocrine Glands; Differential Diagnosis of Endocrine Disorders, *Endocrinology* 13: 327 (July-Aug.) 1929.

2. Barker, L. F.: *Endocrinology and Metabolism*, New York, D. Appleton & Co. 1: 177, 1922.

One of the eight patients gained 20 pounds (9 Kg.); but, since he had lost 15 pounds (6.8 Kg.) before castration, the actual gain was only 5 pounds (2.3 Kg.). All the others gained 20 pounds or more, the maximum increase being 30 pounds (13.6 Kg.). One patient was 10 pounds (4.5 Kg.) under his average weight, which may have been due to the castration, although his habitus could still be classified as pyknic. The second of the two who lost weight had been losing for at least a year prior to orchidectomy. The weight loss was apparently not accentuated by the operation and was due, at least in large part, to dietary deficiency.

Skeletal Changes.—There were no gross skeletal changes in this series comparable to the changes seen in prepubertal castrates.

Skin.—The skin appeared somewhat atrophic and was thin, slightly dry and very finely wrinkled in eleven cases. It had usually a pale or pasty sallow appearance. In one case the skin was more coarsely wrinkled and of the senile type. There was no dystrophy of the finger nails. The teeth did not reveal any trophic changes and were not loose.

Thyroid.—The thyroid gland was considered to be of normal size or smaller than normal in all but one case, in which there was diffuse smooth enlargement to two or three times the size of the normal gland.

Pituitary.—One of the effects of castration in animals is enlargement of the pituitary gland, but the studies of the eyegrounds and visual fields of this group of castrates failed to reveal any significant changes clinically. Roentgenographic studies of the sella turcica were made in ten cases. Nine yielded normal pictures. In one patient, roentgenograms of the sella turcica on two occasions, five and six years after castration, showed some erosion of the clinoid processes. In this instance it is a matter of conjecture as to whether the pituitary enlargement was influenced by the castration or not, because it had been noted during physical examination that the patient had features suggestive of early acromegaly. Acromegaly has not been reported as a consistent sequel of castration, and it appears likely that other factors were prominent in the production of the pituitary enlargement observed in this case.

Other Organs.—Except for the fat deposits in the breasts and around the abdomen there were no physical abnormalities of the chest, lungs, heart or abdomen referable to the hypogonadism. Neurologic examination showed normal results.

BIO-ASSAYS

Comb-Growth Promoting Substance.³—Bio-assays for the comb-growth promoting substance in the urine were done in eleven patients and the amount of the substance in the blood was determined in eight cases. Androten was constantly absent. The method of extraction and assay have been described previously.⁴

Gonad-Stimulating Principle of the Urine.—Engelbach⁵ stated that an "excess amount of pituitary sex

hormone has not been demonstrated in the male castrate," but in our series of twelve cases a tendency to an increase in gonad-stimulating principle of the urine following castration in the male is evident. In eight of the nine patients who were subjected to the Friedman test there was definite evidence of increased gonad-stimulating principle in the urine, as compared to similar tests on normal men.

OTHER LABORATORY DATA

Dextrose Tolerance Tests.—The dextrose tolerance was considered normal in six cases. One patient was known to have diabetes, while two others showed an increased dextrose tolerance. Another patient showed a tendency toward relatively high blood sugar. At one estimation after operation the blood sugar was 179 mg. per hundred cubic centimeters three hours after eating, whereas the average estimation before castration was 108 mg. per hundred cubic centimeters.

Body conformation and distribution of hair in a typical case of adult hypogonadism resulting from castration.

Rowe¹ observed that castration does not change the galactose tolerance in males. The galactose tolerance has not been determined in our cases.

Basal Metabolism.—The basal metabolic rate tended to be low in this series of cases. In seven the rates were decreased to -14 or less, the lowest being -21 . One patient's rate was $+5$ per cent and another's was 0 per cent. It is interesting in this connection to note that the basal metabolic rate of one patient was -7 until six months after castration, whereas a year later it had fallen to -21 .

Blood Chemistry.—Serum calcium estimations⁶ in eleven cases were all within the normal limits. It is obvious that the amount of testicular hormone in the body influences bone growth as judged by the skeletal changes following castration early in life. If such changes are due to the alteration in the calcium metabolism and if similar metabolic changes take place in late castrates, they are not reflected in the total serum

3. We believe that the comb-growth promoting substance in extracts of male urine is a testicular hormone, because it has been demonstrated to be present in the blood, urine and spinal fluid of normal men but has been shown to be markedly diminished or absent in these body fluids of castrates. Measurable quantities of comb-growth producing substance have been demonstrated in some cases of castration in both sexes. It has been shown to be identical with similar extracts prepared from testes as judged by all known physical, chemical and physiologic properties.

6. Clark's modification of the Kramer Tisdall method for estimation of the serum calcium was used.

calcium or total inorganic phosphate levels. The blood phosphate levels are 4.0 to 4.3 per cent in four cases. These are considered to be about the upper level of normal.

The cholesterol showed a tendency to be increased in the circulating blood and, with replacement therapy, to approach the normal level. It was above 200 mg. per hundred cubic centimeters in eight of the twelve cases, and rose to 400 mg. in one case.

We cannot draw any conclusions about the nitrogen metabolism, because in our series the nitrogen intake was not controlled. However, this feature has been studied by others. Korenchevsky⁷ observed a fall of nitrogen metabolism in the "fat" castrated dog and little or no fall in the "thin" type.

The blood counts showed no significant deviation from the normal

TREATMENT

In a few of these cases an attempt has been made at substitution therapy, with androgin, the male sex

the penis. Shortly after the operation he began to have severe hot flashes several times daily associated with nervousness, sweating and fatigue. Before 1925 he had weighed about 150 pounds (68 Kg.). Since the onset of the tuberculosis he had gained steadily. In March 1932 he weighed 174 pounds (79 Kg.). The increased fat was distributed chiefly about the breasts, abdomen and hips, as shown in the illustration. The scalp hair remained normal, and the beard growth may have been retarded somewhat. According to the patient's statement, the limbs and torso had previously been hairy, but within a year after castration hair on the body had practically disappeared.

At examination the patient was alert and cooperative. His skin was sallow, dry and of fine texture and showed peculiarly fine wrinkles. The scalp hair was normal and the beard tended to be slightly scant. There were a few short sparse hairs about the nipples and the axillae, and the pubic hair was scant and the distribution was of the feminine type. The examination of the eyes revealed the presence of the physiologic cup and ring; the lamina cribrosa sclerae was not seen. There was some retraction of the disks upward and outward. A slight parafibrosis was seen in both eyes but in the opinion of the ophthalmologist there were no significant changes. The visual fields were normal. There was a palpable, smooth, diffuse

hormone prepared from urine.⁴ When sufficient material was available for adequate dosage, there was considerable improvement in the subjective symptoms of the hypogonadism. These results have been most encouraging, but it is too early to evaluate accurately the benefits that may be anticipated from this type of treatment.

The pertinent data in this group of cases are shown in the accompanying table. The following case history is typical for the group:

REPORT OF CASE

A married man, aged 33, had a bilateral orchidectomy in 1925 for tuberculous orchitis. Following the operation signs of pulmonary tuberculosis developed, but there has been no activity of the pulmonary disease since 1929. After the operation libido was greatly diminished but sexual potency, although diminished, persisted and he had been capable of intercourse every two to three weeks. He had a normal climax of sensation and the rhythmic contraction but he believed that ejaculation did not occur. There had been considerable atrophy of

enlargement of the thyroid, two to three times the size of the normal gland. There was no sign of activity of the pulmonary tuberculosis. The scrotum was empty and the penis smaller than normal. The prostate was from one-fourth to one-fifth the usual size. It was flat and solid but poorly defined. Vigorous massage failed to express any secretion.

The pulse rate was 80 and the blood pressure 120 systolic, 72 diastolic. A roentgenogram of the chest showed old healed tuberculosis. Roentgenograms of the sella turcica showed no abnormality. The basal metabolic rate was minus 16 per cent. Urinalyses, blood counts, and Wassermann reactions were normal. The dextrose tolerance was increased. Blood sugar estimations fasting and at the end of one-half hour, and at intervals of one, two, three and four hours after the oral administration of 100 Gm. of dextrose were 80, 116, 98, 82, 65 and 75 mg per hundred cubic centimeters. The blood cholesterol was high, 250 mg. per hundred cubic centimeters. Otherwise, chemical analyses of the blood for urea, uric acid, creatinine, nonprotein nitrogen, chlorides, calcium, phosphorus, proteins, albumin and globulin showed no deviation from the normal.

The Friedman test showed that there was an excess of gonad-stimulating principle in the urine. Bio-assays of the blood and urine failed to reveal any male sex hormone.

⁷ Korenchevsky, V. The Sexual Glands and Metabolism. I. Influence of Castration on Nitrogen and Gaseous Metabolism, *Brit J Exper Path* 6: 21-35 (Feb.) 1925

After treatment with androtrin, the patient first noted an increase in energy. Later the nervousness disappeared, but the hot flashes, although diminished, persisted in a mild form. After treatment had been carried out for about a month there was marked increase in libido and potency, and sexual dreams occurred.

Physical examination has not revealed any change except for improvement in the color of the skin. The only alteration in the results of the laboratory examination was reduction of the blood cholesterol from 250 to 184 mg per hundred cubic centimeters.

Clinical Notes, Suggestions and New Instruments

A PHASE OF STERILITY

CHARLES H. BIRNBERG, M.D., BROOKLYN

The phase of sterility to be discussed is familiar to all: "sterility in apparently normal women." A series of eighteen cases is presented. The results of treatment were so gratifying that a presentation of the observations and the method of treatment may be of interest even though the series is small.

On examination, these patients showed no evidence of glandular dysfunction. The cervix, uterus and adnexa revealed no gross pathologic changes. The tubes were patent and examination of the husband's spermatozoa as to size, shape number and motility all proved normal.

The periods of sterility ranged from four to eighteen years. All known methods of treatment had been previously tried without success. These included dilation and curettage, artificial insemination, glandular therapy, corrective exercises, pessaries, diet and tubal insufflation.

was experienced in passing a fine probe. The course of the canal, instead of being straight, was slightly deviated. The displacement of the uterus, usually very slight, varied. The most common displacement was retroversion.

TREATMENT

Before treatment was instituted, all patients were roentgenographed to determine the patency of the tubes.

A, eccentric os at 11 on the clock dial, *B*, deviated cervical canal

The treatment in all these cases was identical. A gradual dilation of the cervix with Hegar dilators was instituted, until the cervix admitted a number 14 dilator. This procedure usually necessitated a period of two months. The early dilation was associated with some degree of pain. The patients presented themselves for dilation once a week. They were

Results of Treatment in Eighteen Cases of Sterility

I. V.	33	7	Both tubes patent	Retroverted	2	10	1	Spontaneous	Male	Yes	No	Yes	Yes	Yes	Yes	Yes

When examined, these patients presented an eccentric external os, a very narrow and deviated cervical canal, and some slight displacement of the uterus. The external os instead of being located centrally as is usually noted, was situated eccentrically; either at 11 or 2, as on the face of a clock, and very rarely at 5. The cervical canal was so narrow that difficulty

was experienced in passing a fine probe. The course of the canal, instead of being straight, was slightly deviated. The displacement of the uterus, usually very slight, varied. The most common displacement was retroversion.

and an eccentric os when they presented themselves for examination at a subsequent visit. The failure in several of these cases to respond to a dilation and curettage previously performed was attributed to this phenomenon.

When the dilation had been completed and the cervical canal permanently opened, the patient was advised to try to become pregnant.

To make this report concise and brief, the table of cases is presented. Two cases in the series were so interesting that a more detailed description is given:

Mrs. M. S., aged 42, was sterile for eighteen years. She had been operated on four years previously for bilateral closed tubes and a plastic operation was performed in the attempt to open them. A roentgen examination performed after the operation revealed a patent left tube. However, all attempts at fertilization, even after operation, failed. As noted in the table, these attempts included a dilation and curettage, artificial insemination, gland therapy and tubal insufflation. Examination of the cervix revealed an eccentrically placed os at 2 on the clock dial. Treatment was instituted Feb. 8, 1932. After eight treatments the patient missed her period and was subsequently delivered of a normal male child.

Mrs. P. G., aged 38, was sterile for fourteen years. Her history was entirely normal. Her menses were regular and normal. Examination revealed a slightly retroverted uterus and an external os eccentrically placed at 11 on the clock dial. She had been extensively treated for her sterility. Two curettages, artificial insemination, prolonged gland therapy, corrective exercises and various pessaries, had been used, without success. Treatment was instituted, June 20, 1927. The patient missed her August period. She was delivered nine months later of a normal male child.

INTRAVESICAL EXPLOSIONS AS A COMPLICATION OF TRANSURETHRAL ELECTRORESECTION: REPORT OF TWO CASES

HERMAN L. KRETSCHMER, M.D., CHICAGO

Having recently had two intravesical explosions with rupture of the bladder at the end of transurethral electroresections, I wish to call attention to this possible complication.

In this connection I wish to emphasize the following points: First, that the explosions occurred at the end of the resections; second, that they occurred in the 313th and 344th resections, respectively; third, that the complication was recognized and the patients operated on immediately; fourth, that both patients made an uneventful recovery following the surgical repair, and, fifth, that one was an intraperitoneal and the other an extraperitoneal rupture.

Practically every urologist, during the course of fulguration treatment of bladder papillomas, has at some time or another experienced small intravesical explosions.

Interesting in this connection is the report of Cassuto,¹ who reported an intravesical explosion in a patient with a middle lobe hypertrophy. He was retouching certain points when there was produced a loud detonation within the bladder. A cystoscopic examination, made eight days later, showed lacerations of the mucosa that extended into, but not through, the muscular coat.

REPORT OF CASES

CASE 1 (313th resection).—A man, aged 65, complained chiefly on admission to the hospital of frequency of urination, both day and night, of ten years' duration. For the past three months, with the exception of the two weeks prior to the explosion when complete retention of urine occurred, he was obliged to void from fifteen to twenty times at night. There had been difficult urination, accompanied by burning, for six years.

The patient was thin and somewhat emaciated; he had evidently lost some weight and appeared to be in poor condition. The liver was palpable; there was tenderness over the bladder and an acute right-sided epididymitis. There was an enormous hypertrophy of the prostate.

A blood count showed red blood cells, 4,450,000; white blood cells, 8,400; hemoglobin, 87 per cent. The blood pressure was 128 systolic, 78 diastolic. The blood chemistry showed non-protein nitrogen, 31.6; creatinine, 1.0.

When the phenolsulphonphthalein test was done the time of appearance was four and one-half minutes; the total output for one hour was 65 per cent.

Examination of the urine revealed blood ++ and leukocytes 1,000 per cubic millimeter, and the culture yielded *Bacillus proteus*.

The patient was treated with an indwelling catheter and bladder irrigations.

Because of the large size of the prostate, a two-stage resection was advised. The first resection was done under nitrous oxide anesthesia, Aug. 24, 1933, at which time a bilateral vasectomy was also done. The second resection was done under sacral anesthesia, October 18. The resection proceeded very rapidly and there was no bleeding. Many of the resected pieces of the prostate were allowed to fall back into the bladder. At the end of the resection these were removed by aspiration with a Bigelow pump, after which a few small inconsequential tags were removed. At this time a loud sound was heard, and the patient stated that he had a severe pain in the abdomen. Irrigation fluid introduced into the bladder through the sheath could not be recovered. A diagnosis of intraperitoneal rupture of the bladder was made and immediate operation was done.

A large stellate tear was found on the posterior wall of the bladder. The tear in the peritoneum was closed with interrupted catgut, as was the tear in the bladder. A cigaret drain was left in the peritoneal cavity for twenty-four hours. The bladder was drained with a suprapubic Pezzar catheter.

The patient made an uneventful recovery and left the hospital, November 12.

CASE 2 (344th resection).—A man, aged 59, admitted to the Presbyterian Hospital, Dec. 13, 1933, complained of symptoms which began about three years before and consisted of frequency of urination both day and night, a very small stream, great difficulty in starting the urinary stream, dribbling, and pain in the back.

On physical examination a slight systolic blow was heard at the apex. There was moderate hypertrophy of the prostate.

A blood count showed red blood cells, 4,400,000; white blood cells, 7,900; hemoglobin, 88 per cent. The blood pressure was 135 systolic, 75 diastolic.

When the phenolsulphonphthalein test was done the time of appearance was six minutes; the total output for one hour was 65 per cent. Examination of the urine showed pus and *Bacillus coli*. The blood chemistry showed creatinine 1.4, nonprotein nitrogen 35.7.

Transurethral resection under sacral anesthesia was done, December 15. The resection proceeded rapidly and there was no bleeding. At the end of the resection the bladder was aspirated with the Bigelow pump. The resectoscope was inserted and a few tags were removed. A sudden dull puff was heard, but it was not as loud as in case 1. Only a portion of the water introduced into the bladder returned. A diagnosis of rupture of the bladder was made and immediate operation performed.

At the operation an extraperitoneal tear was found in the dome of the bladder. This was repaired. The bladder was drained with a suprapubic Pezzar catheter and the space of Retzius with Penrose tubing.

The patient made an uneventful recovery and left the hospital on the twenty-second day.

SUMMARY

1. In both cases there was a very small amount of bleeding.
2. The fragments of resected prostate were aspirated with the Bigelow pump.
3. After the aspiration, a few tags were removed with the resectoscope.
4. Both complications occurred well along in the series of resections.
5. Great care should be exercised in removing frequently the gases from the bladder. If the fragments are aspirated with a pump, thorough irrigation should be done to remove the mixture of gases.

1. Cassuto, A.: J. d'urolog. 22: 263 (Oct.) 1926.

6. Preferably, after aspiration, no further resection should be done.

7. This complication in no way detracts from the value and merits of this method of treatment.

CONTROL OF AMEBIC DYSENTERY

CLINICAL LECTURE AT CLEVELAND SESSION

G. W. MCCOY, M.D.

WASHINGTON, D. C.

AND

A. J. CHESLEY, M.D.

ST. PAUL

The papers by Drs. McCoy and Chesley and Dr. Lynch in this issue are part of a series of clinical lectures on amebiasis read at the Cleveland session. Of the other five papers, those by Drs. Craig and Simon appeared last week and those by Drs. Melency, Magath and Reed will be published next week.

Dysentery has been a well recognized clinical entity for centuries. It was not, however, until the latter half of the nineteenth century that the differentiation of specific etiologic agents, *Endamoeba histolytica* and *Eberthella dysenteriae*, was recognized. In the present discussion we are concerned only with the amebic type of infection.

The outbreak which had its focus of origin in Chicago in the summer of 1933 and which, on the basis of present evidence, seems to have been due largely to contaminated water, has stimulated and renewed the interest of both physicians and health officers in amebic dysentery. Because it is the first recorded instance in which amebic dysentery could be said to have occurred in such explosive epidemic form, this unusual outbreak has focused attention particularly on the mode of transmission and the means of prevention. Indeed, the extensive studies made promptly by the Chicago board of health, on recognition of the epidemic, later reviewed and confirmed by a special committee appointed by the Chicago health commissioner under counsel of the committee, have been extended and continued. These studies have yielded impressive lessons for the clinician, the research scientist and the student of preventive medicine. The clinician has learned that amebic dysentery must be thought of when abdominal conditions not otherwise explainable are encountered. The recognition of amebic dysentery is especially important, since specific treatment properly applied is usually successful. It is not only the internist who must be alert but the surgeon as well, since the experience in the Chicago outbreak has emphasized the fact that not a few cases of amebic dysentery are readily mistaken for conditions that require surgical treatment, such as appendicitis, cholecystitis, ulcerative colitis, hemorrhoids, and malignant growths, while it is well known that surgical intervention in either acute or chronic cases of dysentery reduces the chances of a favorable outcome.

The research worker wants to know more about the possible difference in virulence of races of amebas,

the life history of the parasite outside the body, and many other unsolved problems.

The health officer finds that he must learn more about the chain of circumstances leading to endemics and the direct cause or causes of such explosive epidemics as the one referred to. When he has this knowledge, the means of prevention can be more readily discovered and applied.

One of the difficulties involved in locating the source of infection in any given case or group of cases lies in the fact that the incubation period is, generally speaking, exceptionally long and most variable. When massive infection occurs it appears that the incubation period may be as short as from seven to nine days. There is good authority for believing that sometimes it may be as much as three months or even longer, though in the recent outbreak in Chicago, in which the incubation period could be calculated fairly satisfactorily, the great majority of individuals known to have developed dysentery became sick within thirty days after infection.

SOURCE OF INFECTION AND MODES OF TRANSMISSION

In amebic dysentery, as in typhoid, the only known true source is the infected human being. The possible modes of transmission generally recognized at present are through the agencies of water polluted with infected human discharges; flies infected from feeding on or by contact with infected human discharges, transferring the infection to food; uncooked vegetables contaminated by human discharges and the human carrier frequently as a food handler. The order of importance of the various modes of infection cannot be given at present. The recent experience strongly suggests that the means of transfer of the infection is not necessarily the same in endemic and epidemic amebic dysentery, that the same mode may not prevail in different epidemics, and that two or more modes may operate in the same epidemic.

Uncooked Vegetables.—These are thought to be a source of danger chiefly when human excreta have been used as a fertilizer. This probable means of transmission can be established only by rigorous epidemiologic and biologic investigations, which we fear have not been made. If, and when, such investigations identify the particular food involved, further infection from this source may readily be prevented.

Flies.—Flies have been incriminated, especially by students of military hygiene, and have often been incriminated also under the conditions of civil life. While suspicion points to the fly as the agent in transmission of the infection, convincing evidence is usually wanting. Transmission by flies should never be assumed simply because other sources of infection are not immediately apparent, but, in the event that flies appear to be the most likely mode of transfer of the infection, the means of prevention will depend on local conditions.

Water Supplies.—When a contaminated water supply is found to be the agent of spread of infection, means of prevention may readily be applied. Boiling, of course, is effective and is frequently used as a temporary expedient, but as a permanent measure the source of infection should be eliminated. For example, it appears most probable that the Chicago epidemic was largely due to a locally infected water supply, through improper and defective plumbing. Obviously, here the

remedy is to correct the faulty installation; to insist that new installations shall be satisfactory and through stated inspections to make necessary replacements.

Slow and rapid sand filtration and chemical treatment of water supplies have not been especially studied from the point of view of the prevention of amebic dysentery, but it is to be noted that the organism in the cyst stage is highly resistant to the usual chemical agents, such as chlorine—so resistant that contaminated water could hardly be made safe by this chemical treatment alone. Since the recognized purification methods, including coagulation, sedimentation and filtration, remove a very large proportion of the bacteria in a water supply, it is for the present assumed that it would remove also at least a corresponding proportion of amebic cysts.

The Carrier Problem.—The consideration of the rôle of the carrier in the spread of the infection has commanded more attention in recent years than all other means of transmission combined. It is so easy to assume that, because cyst carriers are found among the associates of a person sick with the disease, the source of infection has been discovered. A difficulty at once arises in the question as to why there is on the whole so little amebic dysentery in the population when it is well known that the proportion of the population recognized as carriers is very high, frequently from 5 to 10 per cent in the United States. This has not seriously discouraged advocates of the carrier transmission theory, who readily assume that only certain carriers are a menace or that only occasionally do conditions favorable to transmission become propitious. For those who advocate the importance of the rôle of carriers in the transmission of amebic dysentery the means for prevention are plain—elimination of the possibility of carriers contaminating the food of others.

While we have no inclination to argue this point with the distinguished proponents of this view, we feel that we may properly point out some of the difficulties encountered in endeavoring to carry out such a program. In the list of these difficulties is the uncertainty of the results of the examination itself. The most experienced workers in this field consider that not over a third, or a half, of the carriers will be disclosed by a single examination and that three examinations will still leave a considerable proportion (estimated at one-fourth to one-third) undisclosed. A second difficulty lies in the question of just where to stop in such an examination. In other words, just who are to be regarded as food handlers? In addition to the groups made up of cooks, waiters and others in hotels, restaurants and other eating places, one must consider whether to include dispensers of soft drinks, butchers, dairymen, milk handlers and, finally, retail grocers. Even if all these are included there is still to be considered a very much larger group made up of domestic employees and housewives. And if one agrees that all these need attention, there would seem to be a fairly good argument for making a "clean sweep" and doing carrier examinations on the whole population.

We have tried to envisage just what it would mean to test the food handlers of a city of half a million. As a very conservative figure, there would be at least 12,000 persons directly concerned in the preparation and serving of food in public eating places. As one well trained, industrious technician can examine thoroughly not more than ten stools a day, the time required to make one examination of all the food handlers in

the population mentioned would be about four years, and to give the minimum of probably useful service, the examinations would require twelve years. This would take no cognizance of the turnover of food handler employees, notoriously large in this class of occupation. The 12,000 food handlers in the hypothetical situation would yield perhaps a thousand carriers, the treatment of whom might present difficulties, although it is realized that the problem of dealing with them would be distributed over a period of years.

From what has been said, it will be appreciated that we consider general examination of food handlers for the detection of ameba carriers impracticable, even if desirable, and we are in doubt as to the desirability of the procedure, excepting under special circumstances, which will be referred to later. Perhaps it might be said that we are not disposed to view carriers of *Endamoeba histolytica* as we do carriers of the typhoid bacillus. The biologic differences of the two organisms are great. Knowledge as to the exact modes of transmission of *E. histolytica* is exceedingly meager. Much study is necessary before it will be possible to estimate even roughly what advantages would accrue to any wholesale attempt to identify ameba carriers, even though the methods of identification were to be perfected to a far greater degree than those possible today.

If epidemiologic investigations point to an individual or a group of individuals as a source of infection of amebic dysentery, obviously means should be taken to identify the carrier, or carriers, through stool examinations. Appropriate steps may then be taken to segregate temporarily and treat the infected persons. Those recognizing the difficulty inherent in the detection and removal of carriers from the food handler group in public eating places suggest another procedure. They would institute a campaign of education of food handlers and employers of food handlers to make the former group "hygiene conscious" with respect to thorough washing of the hands with hot water and soap, or even with disinfectants. This appears to be an admirable program, though presenting some difficulties of accomplishment, not the least of which may be the frequent lack of conveniently located and adequate hand washing and toilet facilities. Obviously the adoption of standard requirements as to hand washing and toilet facilities and the enforcement of their use would definitely minimize any possibility of transmission through food handled by carriers.

An interesting feature in connection with the carrier state lies in the tendency for the infection to spread within a family. According to good authority it is not unusual to have most of the members of a family infected, although it may be impracticable to say in which member infection originated.

Control of Acute Cases.—The clinical case of dysentery is regarded as not a source of danger by most students of the subject, and experience seems to bear this out. Multiple clinical cases with evidence of transmission from person to person are unusual. Cases of the disease are treated in general hospital wards without evidence of transmitting the infection.

Whether any special precautions need to be taken with the bowel discharge in active cases is open to question. The accepted lack of hazard of clinical cases is often explained by the fact that the motile forms (trophozoites) die soon after discharge from the

bowel; however, motile forms and cysts are frequently discharged at the same time in clinical cases. Stools should be treated with a disinfectant to be on the safe side, especially if they are likely to be exposed where flies may have access to them. Here again intensive biologic studies should be of value.

The carrier, on the other hand, must be considered from a different point of view; that is, in regard to the public health aspects of the condition. Students are divided in opinion as to whether or not there are carriers who harbor the parasites and discharge cysts but who remain quite free from any form or symptoms of the disease. True, this point is somewhat academic, but there is no doubt that there are many carriers who suffer no inconvenience. The problem here is What should be one's attitude to such persons with respect to treatment? Should treatment be advised or should the carrier condition be ignored? There is no doubt that in these individuals symptoms of dysentery occasionally develop; indeed, there have been numerous examples in which amebic abscesses of the liver have developed without previous recognizable symptoms of dysentery. As the treatment, by means of several drugs, is relatively safe and quite effective, the situation requires that the hazard of latent infection be explained to the carrier and that he be advised to submit to treatment.

Thus it is that we have endeavored to point out the difficulties which confront the health officer in an earnest endeavor to control amebic dysentery. At the same time, realizing the lack of precise knowledge as to the transmission of the infection, we feel justified in urging moderation in measures that may be adopted. Some states and some local jurisdictions have taken measures that, from the point of view of the individual subjected to them, are truly harsh and, from the point of view of the informed student and observer are unwarranted. We know of quarantine being imposed on the patient and the other members of the family, even to the exclusion of the children from school.

The following quotations from requirements illustrate what we regard as unnecessarily severe measures. One city has the following requirements:

The patient must be isolated during the acute stage of the disease. Bacillary as well as amebic cases are to be placarded.

Carriers, not food handlers, of amebic or bacillary dysentery, cannot be released from observation and from modified quarantine until twelve successive authentic specimens of freshly voided feces, taken one month apart and examined in the City Laboratory, give negative results for *Endamoeba histolytica* or dysentery bacilli, respectively.

Any food handler must show by laboratory test that he is free from *Endamoeba histolytica* or dysentery bacilli, and must not live on the premises with a case or carrier. . . . Public food handlers whose stools on examination are found to contain the *Endamoeba histolytica* or cysts shall not be permitted to continue in their vocation until treatment and twelve successive negative cultures, taken one month apart, have determined that they are free from the *Endamoeba histolytica* or cysts, he may then return to work and submit a culture every six months.

One state has the following requirements:

Cases of amebiasis are not to be released from isolation until two successive laboratory examinations made on specimens of stools taken one week apart show no *E. histolytica* present.

Carriers shall not be released from isolation and control until four successive authentic specimens of stool give upon laboratory examination negative results to *E. histolytica*. These specimens are to be taken one week apart.

Our previous experiences lead to the conclusions that such drastic restrictions are unnecessary; that further epidemiologic and biologic studies are necessary for the guidance of the health administrator in the control of food handlers, but that, when the epidemiologic investigation indicates the possibility of a carrier in an individual or in a group, the identification of the carrier should be attempted and the carrier, if found, appropriately restricted and treated.

What has been learned from the Chicago epidemic should serve to stimulate greater zeal in the protection of water supplies, with special reference to the distribution systems as well as the general supply itself. The larger cities in which the myriads of intercommunicating pipes, both public and private, supply the multiplicity of demands for water for numerous purposes other than for consumption, as for industrial purposes, cooling, flushing, sprinkling, fountain jets, and the like, would probably present the greatest possible hazards. The smaller cities and villages are not free from similar dangers. Old installations and any system under stress of overdemand may menace health. To insure safety there should be no physical connection between water supply systems that are safe for domestic use and those that are unsafe for domestic use.

The recent experiences also indicate that it is not too early to point to the goal of requiring that all rooms used for culinary work and for the storage of ready-to-eat food be properly constructed and located above the ground level, which would obviate the possibility of sewage flooding such rooms.

National Institute of Health.

PROLONGED INFLUENCES AND COMPLICATIONS OF INTESTINAL AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

KENNETH M. LYNCH, M.D.

CHARLESTON, S. C.

Let it be said at the outset that what is meant here by the term amebiasis is the condition of infestation of the human intestine by the protozoon *Endamoeba histolytica*. There may be some question as to whether this conception is too limited, whether other amebas should be included, but proof of that is lacking, and this working hypothesis is acceptable.

In spite of readily available information to the contrary, it remains the common conception that this state of parasitism is rare outside tropical regions. It may be reasonably calculated, from surveys in widely separated localities, that from six million to twelve million people in the United States are the hosts of this pathogenic organism.

The difficulty in accepting this apparent fact has been, no doubt, because of the prevalent conception that amebiasis consists of amebic dysentery, whereas in fact that phase constitutes the uncommon acute flare or end result of the parasitism and is probably largely dependent on complicating bacterial infection. Amebic dysentery is by no means common in this country, even in at least some sections of the so-called subtropical South, and to emphasize the danger of it becoming so may not only be a mistake but a means of continuing the sub-

ordination of the main problem. The larger problem relates to the state of prolonged infestation or chronic amebiasis, and this state is the phase of amebiasis least well understood by all and commonly without place in the conception of the general practicing profession.

For the purpose of this limited discussion of intestinal amebiasis it is necessary to call attention to the fact that the infection or infestation is essentially concerned with the large intestine, from the ileocecal valve to the anus. This is the natural habitat of the ameba, although at times the terminal ileum may be included. Here it becomes seated after ingestion, and here it prospers in variable condition, in accordance with factors still obscure to our knowledge. The whole story of what it may do here is not known.

The lack of knowledge has to do mainly with whether this ameba is an obligatory, facultative or accidental tissue invader, for it is apparently only in the event of penetration of the mucous lining and invasion of the tissues of the wall of the intestine that it becomes an actual disease producing agent.

There is still serious question as to whether this ameba may live at times, or in some hosts entirely, as a lumen dweller. This is a very important question, since on it hinges the individual problem in many cases. I have paid some attention to this question during routine necropsy work for a number of years, and, while no conclusion is now possible, a definite impression has been arrived at that *Endamoeba histolytica* may be only a lumen dweller frequently, and possibly in some hosts entirely so. That is not to say, however, that even so it cannot elaborate toxic substances absorbable from the intestinal lumen. Craig's complement fixation test demonstrates that humoral absorption of amebic products occurs and that there is some antibody production by the host; but whether it is only on the occasion of actual tissue invasion by the ameba is not known. The foundation of James's belief that amebiasis constitutes a condition of more importance to the human race than any other protozoal disease, even than malaria, and that it presents a disease as protean in its manifestations as syphilis itself must rest largely on the proposition of obligatory tissue invasion by the ameba and of humoral absorption of toxic products.

Once present in the intestine, the duration of parasitism by *Endamoeba histolytica* is indefinite, the possibility and actuality of its influence therefore being characteristically prolonged. An understanding of what may occur during its course is necessarily dependent on knowledge of the behavior of the ameba in its natural habitat, the large intestine.

It is capable of entering by its own efforts a mucous membrane previously normal. In the ordinary sense, therefore, it is not an accidental tissue invader. However, how thoroughly it accomplishes this is apparently dependent on factors unknown, which may be, in a sense, accidental. In consequence, the incubation period of the disease is indefinite and commonly is quite prolonged.

In a certain number of the parasitized there may be no evidence of resulting disturbance, this constituting the symptomless carrier state. Since it is not known at what time actual disease may occur in such cases, the parasite constitutes for the host concerned a constant personal menace, while possible transmission to others makes this condition of public concern. As long as such a carrier may be under close medical observation

there is apparently little or no urgency about the matter, so far as he is concerned.

In a certain number of cases quite active invasion by the ameba takes place, at a variable time, with the production of amebic dysentery. While it is not the province of this discussion to deal with that phase, it is necessary to draw the picture of what may subsequently occur largely from the knowledge obtained in study of that condition, since little opportunity is given to study the intestine of the human being except after death and since the parasitism is usually in this phase at death, no matter how long its duration.

The ameba penetrates the epithelial lining of the intestinal mucosa, apparently either on the surface or within the gland crypts, more particularly the latter, in my observation. It is a motile organism, and the inflammatory hindrance to its further penetration is not so great as against bacterial invaders generally. Its travels are slow; it produces a histolyzing substance that destroys fixed tissues within which it lives. When the invasion is active and large the characteristic acute ulcerative colitis results, and the clinical state of amebic dysentery, a humoral toxemia, and a fertile ground for secondary bacterial invasion.

BACTERIAL COMPLICATION

Associated bacterial infection in acute and probably in chronic amebic colitis is not infrequently an important complication.

Such bacterial complication may play considerable part in deep and extensive ulceration and in sepsis, in a nonspecific way. In such incidental infection, streptococci and the colon bacillus play important rôles. The rare complication of large, or even fatal, hemorrhage is the result of active erosion of vessels, in which bacterial action may be important.

A not uncommon coincidental or complicating specific infection of dysentery bacilli is an important event. Confusion may result from simultaneous infection by these two entirely different agents of colonic disease, in either acute or chronic form, unless their common association is realized. Treatment of either is hindered by the presence of the other. A case of chronic amebiasis with complicating acute bacillary dysentery may be diagnosed amebic dysentery, in which case treatment designed for the latter would have no effect on the dysentery. Failure of treatment in a case of dysentery should lead to investigation for dysentery bacilli, regardless of the presence of *Endamoeba histolytica*. Incidentally, bacillary dysentery is probably frequently erroneously diagnosed amebic dysentery on the identification of common harmless *Endamoeba coli* as *Endamoeba histolytica*.

PERITONITIS AND EXTRA-INTESTINAL ABSCESS

It is as a result of active invasion by the ameba itself that the most important complications arise, no matter whether they are exhibited during the acute clinical phase or not. The most immediately serious relate to deep penetration into or even through the wall of the colon, sometimes with perforation and bacterial peritonitis, sometimes peritonitis without complete perforation. Whether the peritonitis may be generalized or localized depends on the location of the peritoneal penetration and the aggressiveness with which it occurs, as well, probably, as the character of the associated bacterial infection. With slow penetration of peritoneal

coverings, the infection may be localized by plastic exudate and one or more peritoneal abscesses may occur, eventually tending to fibrous localization and extensive fibrous matting in the immediate abdominal area or areas. With more abrupt perforation or rupture of colonic peritoneal surfaces, especially in the upper abdominal region, generalized acute purulent peritonitis will usually occur.

It is quite important, as well, to recognize that penetration and perforation of the wall of the colon in its posterior aspects may occur, carrying not only amebas but also bacteria, with the production of tunneled abscesses in the retroperitoneal region, not infrequently of remarkably extensive proportions and with the probable consequence of generalized sepsis. Prolonged amebic colitis of continuous or intermittent clinical character may come to this fatal issue.

ABDOMINAL ADHESIONS

As a result of extension of the infection to the outer coat of the intestine, with or without actual perforation, an important complication of either acute amebic dysentery or chronic amebiasis is the production of adhesions between the colon and coils of small intestine or other peritoneal surfaces. This may be over a single peritoneal area, it may be in several locations, and it may be quite extensive, with firm fibrous matting between the colon, over more or less of its entire course, and adjacent surfaces. Such adhesions are naturally of more or less permanent character and may exhibit their sequelae after eradication of the ameba and apparent recovery from the disease. The attendant dangers of intestinal interference and of actual obstruction or strangulation are quite obviously of prime importance.

LIVER COMPLICATIONS

In consequence of the position of the infection, a complication of the acute phase is so-called acute hepatitis, with swelling and tenderness of the liver. Whether this state is dependent on actual transportation of amebas to the liver or only of amebic or other products is not clear. It by no means necessarily results in amebic abscess and may therefore be mainly the result of portal drainage of the products of the amebas or of the colitis. It appears to be quite susceptible to treatment with emetine.

Amebic abscess, the better known liver complication, is a natural result of amebic colitis. The amebas commonly penetrate into the portal vein branches in the invaded colon wall and the number of instances of their transportation to the liver is probably not well represented by the comparatively uncommon survival and production of an abscess-like area of liver necrosis, comparable in its manner of development to the intestinal ulcer. When this does occur it becomes a very important event. At the time when evidence of this complication is produced, it may apparently have no relation to acute intestinal amebiasis: it is probably more the result of that state, however, than of the strictly chronic form. One must be on guard against this complication in a known amebic infection, while the occurrence of an apparently primary liver abscess should lead to investigation of the stool and intestine, no matter what the geographic origin of the case may be.

Other more distal complicating events of amebic origin are comparatively rare and not to be anticipated. The ameba is not commonly distributed beyond the liver,

at least in disease producing proportions. Amebic abscess of the lung, possibly with even further extension in the thorax, is usually the result of penetration of the diaphragm and base of the right lung from amebic abscess of the liver, while amebic abscesses of the brain, testicle, or other areas are still more uncommon occurrences, from blood borne dissemination, and amebic ulcers of the skin are extensions from sinuses resulting from opening an infected colon or liver. All are, of course, important when they occur, and it is important to identify the nature of the offending agent and relate it to intestinal amebiasis.

AMEBIC APPENDICITIS AND INTESTINAL GRANULOMA

Two complicating events, of direct relation to the intestinal invasion, are infection of the vermiform appendix and amebic granuloma of the colon. Amebic appendicitis is a natural extension from the colon and is usually continuous with amebic ulceration of the cecum, although it has been reported as occurring independently of neighboring cecal ulceration. In view of the tendency of amebic colitis to be prominent in the reservoir portion of the large bowel, it should not be surprising if amebic appendicitis should be a common companion of amebic typhlitis. As an observable matter, however, it seems that except as a part of active amebic colitis it is comparatively unimportant. In study of some thousands of appendixes removed at operation I have never recognized an amebic appendicitis, although amebas have been seen in the lumen. That is not to say that a bacterial appendicitis may not be imposed on an amebic infection so as to hide it. However, it will require much further evidence to show that any material part of common appendicitis is of such origin or association.

From a practical working standpoint it is unnecessary to take amebic infection into account in the actual case of acute appendicitis demanding operation, except in a case of known amebic dysentery. It is important, of course, to take the ameba into account in the study of the appendix and in the event of continued intestinal trouble following acute appendicitis or in the clinical suspect of so-called chronic appendicitis. It is possible, although unproved, that an amebic harbor in the appendix may be more difficult of control than in the intestine proper.

Amebic granuloma of the colon has been recorded as a complicating event, particularly of prolonged amebiasis. In its occurrence there may be confusion with carcinoma or with a localized syphilitic or chronic tuberculous lesion, while it may be productive of intestinal occlusion and obstruction. In case of a granulomatous ulcer of the colon the possibility of amebic origin should be taken into account. As a condition to be separated from regulation amebic ulcer and occasionally related intestinal strictures, it will not be commonly encountered.

PROLONGED AMEBIASIS

It is in the minds of close students of intestinal amebiasis that what usually happens in the natural prolonged state of this infestation is the recurrent production of invasion of the lining of the large intestine, of proportions insufficient to produce a characteristic clinical disease but a chronic local disease and low grade systemic toxemia; that the nature of many obscure colonic and associated constitutional states of illness may be solved by proper examination of the stool and the large bowel.

While it is not my purpose to discuss this apparently common and important chronic intestinal amebiasis in detail here, it must be said that it is a most fertile field for erroneous diagnosis and treatment. The clinical picture is indefinite, constituted mainly of a below-par state, usually with abdominal soreness, tenderness, or pain, perhaps with neuritis, neurosis, joint and muscle pains, and other vague and indefinite symptoms. In its evaluation, roentgen study of the colon is most important but not in itself conclusive, while sigmoidoscopic examination is of great advantage in determining lower bowel involvement. Diagnosis must depend on reliable identification of *Endamoeba histolytica* in the stool; and although the presence of the ameba does not positively prove the case, it at least warrants therapeutic attack. The diagnosis of intestinal amebiasis, no matter how clear the clinical state may appear, in the face of persistent absence of the ameba is not justifiable. It is equally unjustifiable to treat a case of colitis, whether dysenteric or not, and no matter how prolonged, without taking into full account the possibility of amebic infection.

Prolonged amebic colitis commonly exhibits recurrences of the active dysenteric state, often, however, of comparatively minor character. This means periods of activity of invasion and extension followed by recuperation and at least partial healing. It appears that in the less aggressive form there is the production of superficial submucosal abscesses and ulcers, healing and recurring, perhaps in the cecum, sigmoid or rectum, perhaps simultaneously in several areas of the colon. The subject of such an infection is in danger of more aggressive invasion and of serious complication at times unforetellable and is therefore practically constantly menaced.

In the more aggressive prolonged disease there are periods of active and extensive ulceration and dysentery with intermissions of arrest and healing, leading into possible cicatrix production, stricture and colonic deformity of permanent and function disturbing proportions.

One has only to see the colon of prolonged amebiasis after extensive fibrosis, the product of healing and segregating reaction, with variable ulceration, contracting scars, strictures and dilatations, to appreciate the difficulty or impossibility of cure of such a condition, even on the eradication of the ameba.

It has not been within the purpose here to discuss either diagnosis or treatment of amebiasis, but any discussion of the prolonged infestation is incomplete without warning of the necessities in both considerations.

Positive diagnosis of intestinal amebiasis cannot be made without determining the presence of *Endamoeba histolytica*: no diagnosis of chronic amebiasis or of any of the complicating events can or should be maintained without this information.

In estimating the influence of treatment, no cure of the infection can be claimed without full proof of the absence of the ameba. Further, in addition to the eradication of the ameba it is necessary to have in mind the nature of the possible damage, in case of extensive and, particularly, prolonged colonic invasion, and the healing, which must be effected before recovery may be claimed. That is to say, when cicatricial deformity of the colon and extensive peritoneal fibrosis have resulted from prolonged or deep and extensive infection, the

damage is more or less permanent, even if the ameba is eradicated; and, further, the elimination of the ameba at this stage is most difficult of accomplishment, and problematic even when apparently concluded.

Medical College of the State of South Carolina.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. H. A. CARTER, Secretary.

LUXOR B ALPINE SUN LAMP ACCEPTABLE

This is a quartz mercury vapor arc lamp designed for therapeutic ultraviolet applications. It is available in two forms, one for direct current 110 volt operation, the other for alternating current operation. It is manufactured by the Hanovia Chemical & Manufacturing Company of Newark, N. J.

The two lamps employ the same type of highly polished chromium steel reflector used on the Super Alpine Sun Lamp.

The hood and reflector may be rotated around the burner and secured in any position throughout an angle of 90 degrees by means of a handwheel located on the right side of the hood. The opening is 12 by 14 inches, and at a distance of 30 inches from the burner a plane surface receives relatively uniform radiation on an area measuring 5 by 2 feet.

The hood is supported on a telescopic upright, rising from the center of the electrical control housing, which is mounted on a tripod base equipped with three rubber-tired ball-bearing casters.

The light generator consists of a highly evacuated tubular vessel constructed entirely of fused quartz and equipped with the W-type Hanovia electrodes. The burner mounting is

Luxor B Model Alpine
Sun Lamp

devised to maintain the burner at the correct temperature for maximum output.

The electrical circuit for the direct current lamp consists of a rheostat and a double poled toggle type switch, the latter being located on the inlet cable.

The electrical circuit for the alternating current lamp consists of a combination alternating and direct current supply to a three poled burner. Its use results in enhanced intensity and efficiency for the alternating current burner, improves steadiness of the arc, insures ease of lighting, and improves burner life.

The Luxor B Alpine Sun Lamp produces the characteristic spectrum of mercury vapor arcs, and the spectral energy distribution is the same as that previously given for the Super Alpine Sun Lamp, a product already accepted by the Council.

The intensity of ultraviolet radiations 1,850 to 3,200 angstroms at a distance of 30 inches from the burner is at least 500 microwatts per square centimeter for the alternating current lamp, and at least 300 microwatts per square centimeter for the direct current lamp.

Operating Characteristics

Alternating Current

Line voltage: 110 to 120 volts 60 cycle (25 cycle requires special equipment)
Starting Current: 8 amperes
Operating current: 5 amperes
Burner voltage: (A. C.) 135 volts
(D. C.) 40 volts

Direct Current

Line voltage: 105 to 125 volts
Starting current: 7 amperes
Operating current: 3 amperes
Burner voltage: 70 volts

The Luxor B Alpine Sun Lamp, therefore, is included in the Council's list of accepted devices.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

HAWAIIAN FINEST QUALITY PINEAPPLE

- (1) AURORA BRAND BROKEN SLICES AND SLICED
- (2) BING BRAND CRUSHED AND TIDBITS

Distributors.—(1) Abbotts Dairies, Inc., Philadelphia. (2) Borden's Farm Products Company of Illinois, Chicago. (3) Borden's Farm Products Company, Inc., New York. (4) The Bowman Dairy Company, Chicago. (5) Capitol Dairy Company, Chicago. (6) Dodds Alderney Dairy, Inc., Buffalo. (7) Driggs Dairy Farms, Inc., Toledo, Ohio. (8) Graffenburg Dairy, Utica, N. Y. (9) Phenix Dairy, Houston, Texas. (10) Reid's Union Dairy, Brooklyn. (11) Willow Brook Dairy, Mount Vernon, N. Y.

Description.—Bottled pasteurized vitamin D milk irradiated with ultraviolet rays (patent No. 1,680,818).

Preparation.—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL, Oct. 7, 1933, page 1155.

Vitamins.—Clinical investigation shows this milk to be a reliable antirachitic agent if the proper amount is used. Contains 135 U. S. P. X (Revised, 1934) vitamin D units per quart.

Claims of Distributors.—Irradiated antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

SNOW KING DOUBLE ACTION
BAKING POWDER

Manufacturer.—The Snow King Baking Powder Company, Cincinnati.

Description.—Baking powder consisting of starch, sodium bicarbonate, sodium aluminum sulphate and calcium acid phosphate.

Manufacture.—The raw materials and ingredients used are purchased under definite specifications for composition, purity, granulation, etc., all of which are checked analytically by the company laboratories to assure conformity with specifications and food law requirements.

Definite quantities of the ingredients are carefully weighed, thoroughly mixed and sifted; the mixture is stored in tanks until satisfactory laboratory tests assuring proper mixing and composition have been made, after which it is automatically filled into cans, which are labeled and varnished. A test baking check is made on each individual batch.

Analysis (submitted by manufacturer).—

	per cent
Total carbon dioxide (CO ₂)	15.3
Available CO ₂	15.1
Residual CO ₂	0.2
Aluminum (Al ₂ O ₃)	5.5
as Al	2.9
Arsenic (As)	less than 1.0 part per million
Calcium (CaO)	1.2
as Ca	0.9
Iron (Fe ₂ O ₃)	traces
Lead (Pb)	less than 2.0 parts per million
Magnesium (MgO)	0.2
as Mg	0.1
Phosphorus (P ₂ O ₅)	3.03
as P	1.3
Sodium (Na ₂ O)	10.9
as Na	8.1
Sulphur (SO ₃)	17.4
as S	6.9
Starch	40.0

Claims of Manufacturer.—For use in all baking and cooking recipes calling for baking powder. The product and ingredients conform to United States Department of Agriculture requirements as expressed in its definition and standard for baking powder. The two acid reacting ingredients for liberation of the leavening gas, because of their different solubilities, produce a "double leavening action" in the dough. The first action releases a portion of the leavening gas in the cold dough; the second releases the remaining gas in the heated dough in the oven.

FONTANA'S SEMOLINA MACARONI BUTTERFLIES
FONTANA'S SEMOLINA MACARONI SEA SHELLS
FONTANA'S SEMOLINA MACARONI DAISIES
FONTANA'S SEMOLINA MACARONI ALPHABET
FONTANA'S SEMOLINA MACARONI
FONTANA'S SEMOLINA ELBOW MACARONI
FONTANA'S SEMOLINA SPAGHETTI
FONTANA'S SEMOLINA ELBOW SPAGHETTI
FONTANA'S SEMOLINA SALAD MACARONI

Manufacturer.—Fontana Food Products Co., San Francisco.

Description.—Macaroni of various sizes and shapes prepared from durum wheat semolina.

Manufacture.—The sifted durum semolina and water, in definite proportions, are mechanically mixed and kneaded. The resulting dough is forced through various dies to form the different shapes of macaroni products, which are dried on racks under controlled conditions and packed in cartons.

Analysis (submitted by manufacturer).—

	per cent
Moisture	12.5
Ash	0.6
Fat (ether extraction method)	0.5
Protein (N × 5.7)	12.9
Reducing sugars as dextrose	0.6
Sucrose	0.1
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	73.2

Calories.—3.5 per gram; 99 per ounce.

Claims of Manufacturer.—Complies with the United States Department of Agriculture definition and standard.

OXALIC ACID IN METABOLISM

Theories that include oxalic acid as an intermediate product of normal metabolism have received little serious consideration, because of its known toxicity. A number of the more popular ideas concerning oxalic acid in foods have been critically evaluated by Kohman¹ of the National Canners Association Research Laboratories in Washington, D. C. Although an accurate, reliable method is not available for the determination of oxalic acid in foods, Kohman has compiled a table presenting a close approximation of the content of this acid in some common foods. Almost every fruit and vegetable contains oxalic acid; pineapple and leafy vegetables, notably spinach, are strikingly high in this respect (from 0.01 to 0.03 and from 0.29 to 0.69 per cent, respectively). The author points out, however, that an individual would be required to consume from 2 to 5 pounds of a food containing 0.5 per cent of oxalic acid in order to secure an amount that might be considered a toxic dose. It appears that there is considerable unfounded misapprehension concerning the evil effects of oxalic acid in the diet.

The ubiquitous distribution of oxalic acid in fruits and vegetables stimulates questions concerning the metabolism of this compound. Recent investigations from Japanese laboratories² have supplied interesting information concerning the origin and fate of oxalic acid in the organism. This acid is apparently a normal product in the animal body, occurring in the blood in a concentration varying from 3 to 4 mg. per hundred cubic centimeters. Whereas a diet of either protein or fat had no effect on the level of oxalic acid in the blood, the ingestion of a carbohydrate diet by human subjects caused a marked rise in the oxalic acid concentration. The intravenous injection of large quantities of dextrose into rabbits resulted in a striking rise in the blood oxalic acid level; maximum values were obtained approximately two hours after the dextrose injection, the concentration thereafter gradually diminishing and reaching the normal level within from five to six hours.

This apparent relationship between oxalic acid and carbohydrate metabolism is of interest in view of the fact that derangements of carbohydrate combustion are frequently attended by an increased excretion of urinary oxalic acid. It has been demonstrated, for example, that insulin effects an increased ability of the organism to burn this organic acid.³

Oxalic acid assumes particular importance in metabolism when its possible effects on calcium utilization are considered. True, the calcium that is so generally ingested in foodstuffs would tend to detoxicate a portion of the oxalic acid present by the formation of insoluble calcium oxalate; the properties of the latter compound make its absorption unlikely. However, this mechanism at the same time deprives the organism of calcium, an element often present in insufficient amounts in the ordinary diet. It becomes evident, therefore, that the metabolic reactions involving oxalic acid may be of several types. Clarification of these processes must await further information regarding the rôle and fate of the acid in metabolism. This type of result would also aid in evaluating circumstances that determine possible deleterious effects of foods with a high oxalate content.

THE NOMENCLATURE OF GLANDULAR PRODUCTS

The novice in endocrinology finds himself bewildered not only by the tremendous number of recent contributions to glandular physiology but also by a new and unfortunately confused vocabulary. Ordinarily the addition of a few hundred words to the dictionary would concern chiefly the lexicographers; but the many names, synonyms (real and alleged) and trade marks in this field are so liberally interspersed in modern medical literature that the latter is all but incomprehensible to any one except an expert. In addition to the many terms invented from time to time by research workers in many parts of the world, the situation has been made even more difficult by the tendency of each of a number of commercial firms to register its own trade mark for a product to which otherwise, in most cases, it has no proprietary claim. The language of medicine appears to have been more burdened than enriched by the new nomenclature.

Perhaps the most striking case in point is that of the use and misuse of the numerous designations applied to estrogenic preparations. These are variously called female sex hormone, estrin (oestrin), follicular hormone, folliculin, theelin (ketohydroxyestrin, estrone), theelol (follicular hormone hydrate, trihydroxyestrin, estriol), and by such trade names as amniotin, progynon, emmenin and menformon. Still other names are employed. Many of the foregoing terms are not satisfactory designations and they may not all be considered synonymous. Theelin and theelol are recognized by the Council on Pharmacy and Chemistry as

1. Kohman, E. F.: J. Am. Dietet. A. 10:100 (July) 1934
2. Suzuki, S.: J. M. Sc. Japan 2:291, 373, 401, 1934

3. De Lucia, P.: Boll. d. Soc. ital. di biol. sper. 4:756 (June) 1929.

nonproprietary names for two crystalline compounds isolated from the urine of pregnant women. When these crystalline substances are referred to they should be designated by these names (English workers subsequently proposed the synonymous terms estrone and estriol). But at the present state of knowledge it is not warranted to refer to the estrogenic agent of unknown constitution in the blood stream, ovarian follicular fluid, certain plants and other sources by these names. All that is known is that these are "estrogenic substances"; they should therefore be so designated, and the source stated, until the chemical relationship of each particular substance to theelin and theelol is established. The only satisfactory method at present available for determining the presence of such agents is the production of estrus (or preestrual changes) in castrated animals. To speak of the "estrogenic factor" in the blood, for instance, is therefore clear, concise and unmistakable. If this factor is later shown chemically to be theelin or theelol, it may then be so designated. Such terms as "female sex hormone" imply more than may be true; there is doubt that such a hormone actually exists. Estrogenic substance may be found in male urine and it has been claimed that a substance having the characteristic actions of the testicular hormone has been obtained from female urine. There appear to be only slight chemical differences among theelin, theelol and the substance crystallized from male urine that affects the accessory male sexual apparatus. It is not known whether the estrogenic substance in male urine has any function in the male organism or whether the principle in female urine having the effects of the testis hormone has any essential activity in the female. It is therefore preferable to avoid referring to either male or female "sex hormones."

The situation with respect to the pituitary is hardly better. Little confusion would exist if it were customary to designate new and relatively impure extracts according to their effects, instead of coining new names for them. Thus such phrases as "growth hormone," "follicle-stimulating factor," "luteinizing principle" and "lactogenic factor of the anterior pituitary" convey the exact meaning intended. They are as clear to the novice as to the expert. In contrast, "prolan" is applied both to the gonadotropic factors of the pituitary and to the anterior pituitary-like gonadotropic principle from the urine of pregnant women; these were once thought identical, but more recent evidence indicates that they are different. "Antuitrin" is a trade name for an extract of the anterior pituitary; "antuitrin-S" is used to designate the anterior pituitary-like gonadotropic factor from the urine of pregnant women. Many other illustrative examples could be adduced.

By the use of short descriptive phrases, preferably instead of coined names but at least in conjunction with them, many unfortunate misapprehensions and much confusion may be avoided.

MAHLON LOCKE—FOOT TWISTER EXTRAORDINARY

The publicity accorded to Mahlon Locke, Canada's newest contribution to faith healing, has aroused great interest among both the medical profession and the public. The profits to be derived from the sale of shoes to persons suffering with chronic diseases affecting the bones and joints has induced many a department store to add a Locke department to its shoe section. Disciples of the Canadian healer journey about with a motion picture film demonstrating Locke himself in action at the shrine in Ontario. In this picture the stage is set for the introduction of Dr. Locke by pictures of trains, motor cars and other means of transportation bringing the searchers for relief from pain and crippling to Williamsburg. Then are seen his diplomas in medicine. The doctor is next viewed at home and one is privileged not only to meet him in person but to view his hands in a close-up, with all the impressiveness associated with the picture of two hands gigantically enlarged to the size of a motion picture screen. The doctor is observed, appropriately enough, leading his prize bull around on a halter. The doctor is then shown at work, sitting in a swivel chair while human beings come toward him from eight radiating paths to put their feet trustingly in his lap. Either just before or just after he receives the feet he also receives a dollar bill, which is deposited in his pants pocket. He then bends the foot outward and downward and the patient moves on. Some sort of an associate bends the hands of the patients and there are adjacent quarters in which women assistants wiggle the arms, bend the neck hither and thither and bend the back of the patient over a table. A few patients are introduced who say that they have been residents in Williamsburg for several years and have been taking the treatments day by day; they assert that their conditions are improved. There is no serious attempt at diagnosis of disease, nothing resembling a scientific study of the anatomy or physiology of the body as a whole—in fact, not even any serious study of the feet.

Then the scenes change to reveal the diploma in shoe fitting, given to those who study under Locke's system, and also a picture of the astute gentlemen who have evolved from this Williamsburg shrine of faith healing a massive shoe business. Such department stores as Marshall Field's in Chicago and Simpson's in Toronto are devoting whole sections to a participation in the profits to be derived from the Locke publicity. Mr. Hearst promotes his *Cosmopolitan* magazine by articles which Rex Beach is writing concerning the foot twister, and newspaper advertisements send prospective readers and applicants for foot twisting and Locke shoes to the *Hearst's International Cosmopolitan* as the accredited publicity source.

It should be obvious to any one that what Locke does is no more than what chiropractic does, much less than what osteopathy does, and probably much the same

thing that Aimee Semple McPherson Hutton, Emile Coué, Alexander Dowie and many of the disciples of Mary Morse Baker Glover Patterson Eddy have done. It represents psychologie suggestion reenforced by the laying on of hands; perhaps in a few instances the pulling of an adhesion such as any masseur might attempt. If bones are put back into place, what makes them stay back? While it pays, it pays handsomely, and when it moves on something else of the same nature usually comes in its place. In better times, institutions for the purveyal of merchandise which have for long held high standards would perhaps have turned thumbs down on such an obviously charlatanic promotion, but in these times the dollars are hard to get and the department stores seem not to be averse to a share in the profits of faith healing.

The activities of Dr. Loeke are a burlesque on the scientific practice of medicine. His promotion is a violation of every traditional, ethical tenet! Were not the results so lamentable, the comedy would be laughable. There are some who say that even psychologie relief for the chronic arthritic patient is worth while, regardless of the means by which it is accomplished. The reaction on the scientific practice of medicine and the chagrin and disappointment of those seriously sick do not permit this laissez faire attitude. Moreover, many a person who might be benefited by scientifically applied physical therapy and by competent orthopedic surgery is spending hard-earned money to make the long trek to Williamsburg in search of a pot of gold which those at the end of the rainbow are quite consistently saving for themselves. If Loeke's practices are right, the medical schools might just as well stop teaching anatomy, physiology, pathology and diagnosis. But they need have no fears. History shows that such charlatans and such systems come and go, while scientific fact and knowledge go on forever.

Current Comment

MOTION PICTURE OF HEAD- QUARTERS ACTIVITIES

From time to time the suggestion has been made that a motion picture be prepared of the headquarters activities of the American Medical Association so that county and state medical societies as well as other organizations might be informed of the nature of the work in the headquarters office. Last year the Board of Trustees appointed a committee, headed by Dr. Austin A. Hayden, to supervise the preparation of a 16 millimeter film for this purpose. The film has now been prepared and has already been shown at a meeting of the Chicago Medical Society and at a meeting of the editors and secretaries of state medical societies. As yet but one copy of the film is available. It shows the personnel of the various bureaus and councils of the Association, the executive officers, the members of the board of Trustees and of the House of Delegates,

the composing, printing, binding, addressing and mailing departments, the manuscript editing rooms and the library, and many other activities of the headquarters office. Arrangements have been made to lend this film to county and state medical societies together with a projector and a screen. Work on the picture is proceeding and it is not yet considered a finished task. It is planned to add pictures of all the different councils and official bodies so that the film will constitute a true record of the history of the Association at this time. Adequate subtitles explain the nature of the work shown, but the affairs are so complex that space is simply not available in a subtitle to indicate fully the significance of the various activities. The Board of Trustees and the office of the Secretary of the Association will be interested in hearing from county and state medical societies or other bodies that are interested in showing this film.

IRON AND COPPER RETENTION IN CHILDREN

As a result of experimental studies during the last six years, the necessity of both iron and copper in the cure of "nutritional" anemia, the condition resulting from the consumption of an exclusive milk diet, has been emphasized. Efforts have been made to cure various types of human anemias by supplementing the therapeutic doses of iron with copper. However, one commentator¹ has stated that the claims for the efficacy of copper in the treatment of clinical anemias have not thus far been convincing. Nevertheless the known indispensability of iron and the possible essential nature of copper lend interest to a recent investigation by Daniels and Wright² of the requirements of these two metals in children. Eight normal children (three girls and five boys) were given an adequate diet, and the total intake, loss and retention of iron and copper were determined in fifteen experimental periods. On daily intakes of from 0.57 to 0.75 mg. per kilogram of body weight there was a considerable variation in retention among the different subjects, the values ranging from 0.12 to 0.27 mg. daily per kilogram of body weight. The conclusion was reached that 0.6 mg. of iron daily per kilogram "should meet the needs for maintenance and growth of the average child of the age studied." With daily consumptions of from 0.069 to 0.113 mg. of copper per kilogram there was observed daily retention of from 0.012 to 0.048 mg. per kilogram, the diets containing the most copper favoring the greater storage. It was tentatively suggested on the basis of the observations that at least 0.1 mg. of copper per kilogram of body weight should be contained in the daily food of children of preschool age. It is of interest that in this investigation almost all (from 93 to 98 per cent) of the excreted iron and the copper appeared in the feces. The fact that on the higher levels of retention of copper there was a fairly close proportion between iron and copper retention (5:1) may indicate that there is in man also an interrelationship between the metabolism of iron and of copper.

SUCCESSFUL INDUSTRIAL GROUP PRACTICE

M. S. BLOOM, M.D.
BINGHAMTON, N. Y.

IN THE JOURNAL, over a year ago, I¹ discussed a plan of industrial group medicine referred to as the Spaulding plan and sponsored by Spaulding Bakeries, Binghamton, N. Y. At that time the plan had been successfully functioning for a full year. The broad circulation of THE JOURNAL, combined with an apparently widespread interest in the question of group medicine, brought inquiries and comments from every section of the United States, and from some sections of Canada. This interest made me wonder whether another article dealing with recent developments in the plan might not be worth while.

The Spaulding plan, of which I am medical adviser, has now definitely passed the experimental stage and has become a permanent organization offering various medical services to employee members of Spaulding Bakeries. I was chosen medical adviser of this plan because the sponsoring company felt that some one with medical training was necessary to administer the medical problems that arose. Apart from my general interest in the practical philosophy of group medicine as exemplified by this plan, my interest is academic.

Concerning this plan, a most significant point to the medical and dental professions is the provision for freedom of choice. It is the operating routine under this plan for officers never to suggest or urge on a member of the Spaulding Employees' Mutual Benefit Association to consult any particular doctor or dentist. When an employee obtains a physician's slip, the employee is simply asked what doctor or dentist he wishes to consult. No other questions are asked. The employee goes to whom he pleases for treatment. Occasionally employees wishing eye examinations, tonsil operations or other procedures ask the secretary or other officers to suggest a specialist. All officers are instructed, however, to give the name of all doctors performing the particular type of service desired but not to recommend any one specialist.

Accordingly, various evils are avoided by following strict rules governing the practice and preservation of the principle of freedom of choice. Under the Spaulding plan there is no possibility of politics playing a part in the choice of physicians and dentists, with a consequent lessening of efficiency in the plan and inevitable criticism by the medical and dental professions. Further, no loopholes are left for the employee to complain if he should not be satisfied with the physician or the service rendered. More important, perhaps, the plan recognizes the integrity and legitimacy of that ethical principle among doctors and dentists that treatment of the sick should be left to professional care and judgment, unhampered by lay intervention or pressure of any kind or sort.

As a result of this unyielding policy not to abridge or attempt to abridge the professional concepts of what is and what is not good medical practice, this plan has earned good will for itself among the doctors and dentists of the community. If I am permitted to make a conclusion before I conclude, it is this—I feel confident that it is possible to provide for satisfactory group medical practice, in some instances at least, without exciting controversy and rancor within the profession and without attempting to usurp from the physician and dentist the power and right to dictate the fundamental principles of professional practice.

Let it first be understood just what the Spaulding plan is and what it does. Then I will draw some broad conclusions, rooted in facts and experience, which indicate or suggest how the machinery of this plan fits social patterns as they exist today.

Briefly, this is the general plan: All employees of the bakery may become members on agreeing to abide by the by-laws and paying their weekly dues. Membership dues are governed by a wage classification of four groups and run from \$0.20 to \$0.45 per week. The company makes an equal contribution; that is, for every dollar in dues paid by the members, the company also contributes one dollar. The company contribution is essential to the financial success of the plan, as few industrial groups indeed could be found to bear willingly the whole burden.

There are now 200 members in the Binghamton division. Members are entitled to major and minor operations, hospitalization for thirty days in any one year (with a three dollar per day allowance for a room), plus all other hospital costs. Both office and house calls are permitted, including services of specialists. All laboratory fees and x-ray charges are paid by the association. Each member is entitled to ten weeks of sick benefits in any one year, these benefits running from \$7.50 to \$20 a week and determined by the member's respective wage classification. Dental services are confined to the x-rays and extraction of teeth. Certain limits other than those mentioned are made for various expenditures. For instance, house and office calls are limited to \$50 a year per member. Total expenditures for any one member are limited to \$350 a year, as provided by state law for organizations not incorporated.

Last December some of the features of this plan were extended to dependents of employees, the services including office calls, the allowance for the cost of an office call toward a house call, and laboratory and x-ray charges. Employees must be members of the general association to be entitled to these services for their dependents, and the additional dues constitute a flat \$0.25 a week for each member. In this case the company contributes one-half the amount contributed by the members. There are now approximately 100 members in the dependents' division, and the number of dependents varies from one to eight per family. When the dependents' division was organized the company had grave doubts of the division's future success, yet in less than a year a satisfactory surplus has been accumulated and further services may be extended as the growing surplus warrants.

With some minor change the general plan was offered to the employees at the Elmira plant of Spaulding Bakeries in December last year, and there are approximately 100 members in this division. Indications are that a protective surplus will have been built up by the Elmira division at the end of the fiscal year. Another division is now being organized in the Oneonta plant and will have a membership of approximately fifty.

This, then, is the Spaulding plan as it exists today. In an article of this kind, much detail must be avoided; hence I have only briefly sketched the plan. The success of the plan in Binghamton led to its adoption by two other firms in the city.

The Agfa Ansco Corporation, manufacturers of cameras, photographic films and other sensitized products, which has approximately 1,000 employees, has had in operation on a contract basis a mutual benefit association since May 1, 1929. May 1, 1933, a project similar to the Spaulding plan was instituted, which has been equally successful.

Truitt Brothers, shoe manufacturers employing 250 people, adopted the plan early in April of this year and is repeating the success of the other group plans.

1. Bloom, M. S.: A New Experiment in Industrial Medicine. J. A. M. A. 100: 1869 (June 10) 1933.

It may be of some interest to point out the percentages of expenditures made under the Spaulding plan for physicians' services, sick relief, hospitalization and dentists' services. They are given in the accompanying table.

Percentage of Expenditures

	Physicians	Sick Relief	Hospitalization	Dentists
1932-1933....	73.2	10.7	8.2	7.9
1933-1934....	66.2	12.3	13.8	7.7

There is no question in my mind or in the minds of the executives of Spaulding Bakeries that the interest and cooperation of the physicians and dentists in a given community are an essential consideration in the success of a plan of this kind. The right of the physicians and dentists to have their ideas known and respected before the plan is launched cannot be disputed. Before organizing a division in any community, executives of the company meet with the local medical society's committee on medical economics to discuss the whole plan and fully explain the details. Where divisions have been established, local physicians and dentists have invariably and enthusiastically approved this organization and have given splendid cooperation. The Spaulding plan has the approval of the New York State Medical Association and of the local medical societies as the plan relates to the ethics of group practice.

If this group plan deserves to be called successful, it certainly should meet rather fully the practical requirements of the profession, the employee and the employer. With the principle of freedom of choice unrestricted, every physician and dentist in the community has an equal opportunity to serve the members. The recognized fee schedule of the community is respected and preserved, and no attempts are made to bargain for medical and dental costs. All the association asks are standard fees for standard services.

Equally significant to the profession is the sureness of collections, because bills are paid fully and promptly. Even in these times the secretary finds it difficult to obtain statements promptly from many members of the profession, perhaps because doctors and dentists are sure of punctual payment. It seems possible that the profession as a whole derives more revenue from the men and women under the plan than if there were no plan. Experience proves that disease is sometimes neglected because an individual fears the doctor's bill. With payment for treatment guaranteed, members go to their physician without fear of the cost, yet few cases have been found in which privileges are abused.

No attempts have been made to analyze the benefits to be derived by the sponsoring company itself. That there is less absence from work on account of illness seems a natural conclusion to be drawn. The medical needs of the employees are certainly better provided for, and proper treatment is not so often neglected. Periodic physical examinations under the plan often disclose neglected conditions, which are pointed out by the examining physician. It has been the experience in organizing various divisions of this plan that a great many minor operations are necessary at first, which would seem to indicate negligence on the part of the individual before becoming a member of the association. It would seem that an employee, largely freed from the burden of unusual medical costs to himself, would be more happy and content in his work, and perhaps more efficient. There is no quantitative method for determining this point.

In the more serious cases it is possible to get medical consultation more quickly, because multiple costs are borne by the association instead of by the patient himself; hence he more readily accedes to the suggestion for consultation. One might perhaps be accused of injecting too much theory to say that

probably the general state of health of the community is raised to some degree by this plan.

It is true that the member pays while he is well and that he must be sick to draw on the treasury. In a sense the plan provides health insurance, but a type of health insurance controlled by the professional community, without benefit to political and lay dictation.

Under the plan, the company provides for all administrative expense, and competent executives are entrusted with the administration of the plan. This is an important phase of the work. The company is just as interested in this department as it is in its manufacturing, sales, accounting and advertising departments. Supervision is close and strict, and the work of the department is executed as quickly and efficiently as in any other department. At this juncture I may draw one of the broad conclusions that were promised. Group medicine, fostered by such a plan, is free from politics.

Each officer in the association has a definite job to perform, and his success in performing his tasks in the association determines his success with the company itself. He is paid for performance, not out of association funds, not because he knew a certain influential politician, but because in the first place he was intelligent and industrious enough to get and hold a business position. His duties in the association are accessory to his regular business duties, and part of them.

Group medicine, provided by this plan, does not attempt to regulate medical practice, does not place in the hands of the layman political power to control the destiny of the medical profession. Free and independent, it leaves the profession to work out its own destiny, to develop its own ethical concepts and to enjoy the fruits of its genius without considerations of political patronage or spoils.

I am making no claim that the Spaulding plan could be adopted universally, in toto, nor am I claiming that, if it were, the problems of providing medical care would be solved. I clearly recognize its limitations and its lack of adaptation to many groups. Nor do I suggest that all-business enterprises possess sufficient generosity and foresight to initiate and administer such a plan. It may be that the natural inclination of the business executive is to overlook all ethical considerations of the profession and the very personal needs and desires of the workers respecting individual medical care. Industrial medicine to such executives means simply going out and hiring professional talent just as their employment department hires stenographers. Under such conditions, treating the sick through respect for accepted standards among physicians and patients is out of the question.

In spite of these and other possible limitations, there are some noteworthy features of the Spaulding plan that do merit more than casual interest because they conform to certain proved characteristics of human nature. First is the absence of politics as a directing force in the plan. Second, the plan does not savor of a health dole. The employee pays part of the cost and feels that he is helping himself, and he is. This makes him self respecting. Free goods and services of any kind never helped build the character of a man, although they may temporarily have relieved hunger pangs. The law of compensation is still inviolate. If one gives a man everything, one takes away his self respect; and when one takes away his self respect, one takes that much character away from the man. Nothing is cherished that is free, that involves no cost, no responsibility and no obligation.

The plan provides that a man pays when he is well, for most industrial workers cannot pay when they are sick. Dues deductions are small and, by the majority of the employees, not missed. How doubly serious is great illness when the patient must lie in bed wondering where the money is coming

from to pay his expenses! How often is he tempted to lie there longer than he should, or arise sooner than he ought? How often complete discouragement accompanies a man back to his feet after a serious illness. I have marveled at the quick intelligence of the average worker when this plan is explained to him. He sees its merits immediately. He sees that no portion of what he pays is diverted to questionable administrative expenditures, elaborate office fixtures and political sinecures. Everything that he pays in belongs to him. The surplus is deposited in a bank and draws interest until needed. The employee is not forced to become a member, not even coaxed. He joins of his own free will and knows what he is joining. He can still go to his own family physician, who has been serving himself, his wife and his children satisfactorily for many years, a man in whom the employee has the greatest confidence.

Finally, the plan boils down to this residue: All along the line, self-respecting men are left to pursue independently their own ideals. They have to do nothing, accept nothing that is repugnant to their own self-felt decision. Is it not better than hordes of political officeholders driving business men, doctors and workers into a tight-fenced enclosure under the guise of offering an extraordinary medical bargain, when as a matter of fact all these groups concerned are deprived of the right to self-determined action?

This plan cannot possibly be stretched to include the chronically sick, the unemployed sick, the sick poor or the malingerers, but it can be extended with limitations to employed groups, and these groups constitute a large percentage of the population. That is, it can be extended when intelligent and generous-spirited employers would like to do it and when employees themselves are ready to receive it.

THE ATLANTIC CITY SESSION

Invitation to Contributors for Program of Section on Surgery

Prevailing concepts of the relative significance of gross and minute normal and morbid anatomy and of normal and morbid physiology are directing, as they always have directed, modes of investigation as well as of practice. Concepts are distorted through failure to collect, to correlate and to utilize information from all sources—in short, to resort to biology for guidance in laboratory and clinic. Presentation and discussion of correlated data will advance working knowledge of fundamental processes productive of health and disease and simultaneously disclose therapeutic principles of widest applicability. The council of the Section on Surgery, General and Abdominal, urges members of the Canadian and the American Medical Association, and not only surgeons, to present papers at the meeting to be held June 10-14, 1935, that will emphasize biologic concepts of health, pathogenesis and therapy.

Processes productive of health are the formation and equable distribution of an adequate volume of good blood. Bernard showed that blood and lymph constitute the internal environment of a body and that balance in and among its constituents is compatible (imbalance incompatible) with health. Numbers of cellular and volumes of noncellular constituents fluctuate with an individual's activities, but alterations do not exceed wholesome limits because of automatic adjustments (Cannon). Similarly, myocardial and vascular activities fluctuate and are restricted within wholesome limits by pressor and depressor automatic adjusting influences. Processes productive of disease cause anomalies (unwholesome surpluses and deficits) in the constituents of the blood or impair the balance in myocardial

or vascular functions. Pathogenic processes, exclusive of those occasioned by trauma, temperature, electricity and so on are primarily nonantigenic or nonparasitic or primarily antigenic or parasitic.

Nonantigenic processes arise from derangement in the divers automatic adjustments constituting the regulatory organization of a body. Consequences thereof are manifest; e. g., in polycythemia vera and in pernicious anemia; in hyper- and hypothyroxinemia and -cortinemia in hyper- and hypo-glycemia, -calcemia, and in the unwholesome sympathinemia, parasympathinemia and adreninemia, provocative of cardiac, vascular and other visceral disturbances (malignant hypertension, peptic ulcer, and the like).

Antigenic processes are caused by presence in blood or lymph of a pathogenic excess of toxic egesta of parasites or of comparable noxious substance (antigens) that cause an overproduction of leukocytes and an elaboration of antibodies. Antigens are in the internal environment from soon after establishment of a fetal circulation until death. Health is maintained by an increased production of leukocytes and an elaboration of antibodies, which in effect produces an antigen-antibody balance. Pathogenic excess of antigens occurs when there is a deficit in antibodies and in some leukocytes and a surplus in other leukocytes, which together create anomalies. Disturbances in myocardial and vascular activities are frequently secondary complications of primarily antigenic processes.

Progressing alterations in the constituents of the blood that have not exceeded wholesome limits usually occur as susceptibility to nonantigenic and antigenic diseases in developing. Anomalies are present when a disease is incipient, progress as the disease advances and regress as it recedes, to disappear with recovery. The practical value of recognition and interpretation of alterations in blood in conjunction with all other data is great. Thus can be recognized earlier the needs for prevention and treatment and the indications for efficacious measures. It is not yet possible to recognize consistently and to interpret accurately alterations approaching anomalies or to interpret correctly existing anomalies in the cellular constituents. Not all constituents of plasma are known and only in a part of those recognized can the volume be estimated accurately. Investigation and discussion of these matters are requisite to a sustained advance in clinical medicine. Authors are invited to submit summaries of their papers as soon as convenient to the secretary of the section, Dr. H. M. Clute, 605 Commonwealth Avenue, Boston, but not later than Jan. 1, 1935. Not all papers will be limited to the subjects indicated. Acceptances will be based on merit, priority and fitness as judged by the council to the end that the program shall, so far as possible be beneficial to all.

J. L. YATES, M.D., Milwaukee.

Chairman, Section on Surgery,
General and Abdominal.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be as follows:

October 18. Keep Fighting Diphtheria, W. W. Bauer, M.D.
October 25. What Is a Serum? W. W. Bauer, M.D.
November 1. The Common Drinking Cup, W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

October 16. Research in Medicine, A. C. Ivy, M.D.
October 23. Reading About Health, W. W. Bauer, M.D.
October 30. Diphtheria Must Go, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Dr. Vinsonhaler Retires from Practice.—Dr. Francis Vinsonhaler retired from active practice, September 1, to devote full time to his duties as dean of the University of Arkansas School of Medicine. Dr. Vinsonhaler has engaged in practice in Little Rock for forty-two years, and since 1927 has been dean of the medical school. He is also professor of medical ethics.

Society News.—The Mississippi County Medical Society entertained members of the faculty of the University of Tennessee College of Medicine, Memphis, in a reunion at Blytheville, September 14; among the speakers were Drs. Benjamin F. Turner, James B. McElroy, William Battle Malone, Joseph A. Crisler, James L. Andrews, Elmer E. Francis and Eugene M. Holder, and Orren W. Hyman, Ph.D. At a meeting of the Greene County Medical Society, September 13, Dr. Jones H. Lamb, Paragould, spoke on the treatment of pneumonia.

CALIFORNIA

Symposium on Heart Disease.—The heart committee of the San Francisco County Medical Society will hold its fifth annual symposium on heart disease, November 21-22. No fee is charged for the course, which is open to all physicians who are interested in diseases of the heart. Further information may be obtained from Dr. Jay Marion Read, 490 Post Street, San Francisco.

Society News.—Ralph W. Chaney, Ph.D., Berkeley, delivered an address before the San Francisco County Medical Society, October 9, entitled "Studying the Oldest Man in Asia," and Dr. Frank B. Young, Long Beach, on "Evidences of Diseased Conditions in Ancient Organisms." At a meeting of the Los Angeles Surgical Society and the Hollywood Hospital staff, October 12, papers were presented by Drs. Arthur E. Guedel on "Cyclopropane Anesthesia"; Joseph W. Warren, "Radiographic Study of the Breast," and Gurn T. Stout, "Physiologic Control in the Use of Gastro-Intestinal Drainage Apparatus."

Research Study Club.—The fourth annual clinical course of the Research Study Club of Los Angeles will be presented in Los Angeles, January 21-February 1. Guest lecturers in otolaryngology will be Drs. Georges Portmann of Bordeaux, France, and John F. Barnhill, Miami Beach, Fla. Guest speakers in ophthalmology will be Drs. Webb W. Weeks, New York, and Harry S. Gradle, Chicago. The courses in dissection, given by Dr. Barnhill, will be offered in conjunction with the University of Southern California Medical School. The fee for the entire course will be \$50. Further information and a detailed program may be obtained from Dr. Donald S. Dryer, 2007 Wilshire Boulevard, Los Angeles.

COLORADO

State Medical Election.—Dr. Walter W. King, Denver, was chosen president-elect of the Colorado State Medical Society at its annual meeting in Colorado Springs, and Dr. Nicholas A. Madler, Greeley, was installed as president. Vice presidents elected are Drs. Royal H. Finney, Pueblo; Charles E. Lockwood, Montrose; Fred A. Humphrey, Fort Collins, and Guy E. Calonge, La Junta.

DISTRICT OF COLUMBIA

Health at Washington.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 29, indicate that the highest mortality rate (18.2) appears for Washington, and the rate for the group of cities as a whole was 10.1. The mortality rate for Washington for the corresponding period last year was 13 and for the group of cities, 10. The annual rate for eighty-six cities for the thirty-nine weeks of 1934 was 11.4 as compared with a rate of 10.9 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

GEORGIA

Tuberculosis Program.—With funds made available by the FERA, the Georgia State Department of Health is carrying out a program to locate and place under care patients suffering with tuberculosis. Ten field nurses and two supervisors have been added to the staff. The nurses organize clinics and do follow-up work in the ten districts into which the state was divided, helping not only to secure medical care for patients but also to obtain financial assistance and to rehabilitate them. In addition, through the family physician the nurses schedule 300 patients a week for examination by the x-ray unit of the state board.

Society News.—Dr. Guy J. Dillard, Columbus, read a paper before the Randolph County Medical Society at Cuthbert, September 6, on pulmonary tuberculosis. The Burke-Jenkins-Screven Counties Medical Society was addressed at Millen, September 6, by Drs. Robert L. Miller, Waynesboro, on coronary thrombosis, and James M. Byne Jr., Waynesboro, angina pectoris. A paper on acute poliomyelitis was presented before the Ware County Medical Society at Waycross, September 5, by Dr. John E. Penland. Dr. James L. Campbell, Atlanta, conducted a symposium on cancer before the Ninth District Medical Society at Gainesville, September 19, and Dr. James E. Paullin, Atlanta, discussed rheumatoid arthritis. Dr. Hugo Robinson, Albany, was elected president of the Georgia Health Officers' Association in Atlanta, August 30; Dr. Silas C. Rutland, La Grange, vice president, and Dr. Millard E. Winchester, Brunswick, secretary, reelected. At a meeting of the Fulton County Medical Society in Atlanta, October 4, Dr. Ebert Van Buren discussed "Pulmonary Tuberculosis Complicating Diabetes Mellitus."

IDAHO

State Medical Election.—Dr. Joseph H. Crampton, Lewiston, was chosen president-elect of the Idaho State Medical Association at its annual meeting in Lewiston, September 8, and Dr. Charles R. Scott, Twin Falls, was installed as president. Dr. Harold W. Stone, Boise, was reelected secretary-treasurer. The next annual meeting will be held in Boise.

ILLINOIS

Society News.—Dr. Harry R. Hoffman, Chicago, addressed the Randolph County Medical Society at Menard, September 27, on mental defects in criminals. Speakers before the Adams County Medical Society in Quincy, October 8, were Drs. Dan G. Stine, Columbia, Mo., on "Value of the Leukocyte Count in Pulmonary Tuberculosis," and Marcus Pinson Neal, Columbia, Mo., "The Leukocyte Blood Pictures in Acute Infections." At a meeting of the Will-Grundy County Medical Society at Joliet, September 26, Dr. Francis L. Lederer, Chicago, spoke on "Cancer About the Head and Neck—A Critical Analysis of the Available Therapeutic Measures." Dr. Frank F. Maple, Chicago, addressed the Fulton County Medical Society, September 27, on "Septic Abortion." Dr. Gilbert FitzPatrick, Chicago, discussed cancer before the Marion County Medical Society, September 27. Dr. Aaron Arkin, Chicago, addressed the Rock Island County Medical Society in Moline, September 11, on lesions of the gastrointestinal tract. Dr. Cyrus C. Sturgis, Ann Arbor, addressed the Peoria City Medical Society, October 2, on "Treatment of Secondary Anemias."

Chicago

Lay Educational Program.—Heart disease will be the theme of an educational program to be presented for the public, October 17, in the Medical Arts Building, under the auspices of the Chicago Medical Society. Dr. Iago Galdston, New York, will discuss "The Nature of the Increase of Heart Disease," and Dr. Newell C. Gilbert, "The Principal Causes of Heart Disease."

Dr. Moore to Lecture at Illinois.—A series of graduate lectures on "The Physiological Basis of Individuality in the Early Embryo" will be delivered at the University of Illinois College of Medicine, October 15-20, by Arthur R. Moore, Ph.D., professor of general physiology, University of Oregon, Eugene. Dr. Moore will present the following lectures on the dates indicated:

The Cytoplasm as a Biophysical System, October 15.
Special Cytoplasmic Structures, October 16.
The Individual in Motor Reactions of Simple Forms, October 17.
Phylogenetic Beginnings of the Central Nervous System, October 18.
Modifiability of Reactions, October 18.

Society News.—At a meeting of the Chicago Gynecological Society, October 19, the speakers will be Drs. Fred L. Adair and M. Edward Davis on "Chronic Atrophic Dermatitis of the

Vulva," and Carl Henry Davis, Milwaukee, "Use of the Colposcope in the Diagnosis of Cervical Lesions." Dr. Fred J. Taussig, St. Louis, will be the society's guest at dinner and the meeting and will discuss the papers. A clinical meeting will be conducted at Michael Reese Hospital in the morning. —Dr. Arthur Steindler, Iowa City, addressed the Chicago Orthopedic Club, October 12, on "Tuberculosis of the Wrist." Other speakers included Drs. Frank G. Murphy on "Traumatic Rupture of Quadriceps Tendon Above the Patella with Surgical Repair" (case presentation), and Edson B. Fowler, Evanston, Ill., "Internal Fixation of Fractures with Horn: Cortico-Medullary Technic."

MAINE

Society News.—Speakers before the Hancock County Medical Society at Bar Harbor, August 15, were Drs. John J. Moorhead, New York, on "Traumatic Surgery," and David Riesman, Philadelphia, "Subacute and Chronic Bronchopneumonia and Its Relation to Disense of the Upper Air Passages." —A symposium on thoracic disease was presented before the Washington County Medical Society in Calais, August 24, by Drs. Bertram L. Bryant, John L. Johnson and Theodore S. Moise, Bangor. —At a recent meeting of the Androscoggin County Medical Society Dr. William H. Watters, Boston, discussed asthma with special reference to the nasal factors.

MICHIGAN

New County Medical Society.—The Van Buren County Medical Society was created at a dinner meeting, recently, when physicians of the county were guests of the county health department and the W. K. Kellogg Foundation. Dr. Arthur A. McNabb, Lawrence, was chosen president, and Dr. John F. Itzen, South Haven, secretary.

Course for Rural Practitioners.—A course in differential diagnosis of communicable and infectious diseases was recently given at the Herman Kiefer Hospital, Detroit, for the physicians of Allegan, Barry and Eaton counties. The course, sponsored by the W. K. Kellogg Foundation, is the second of its kind. For the first, the foundation sent physicians from these counties to medical centers in Chicago and Rochester, Minn. Dr. John E. Gordon, epidemiologist, Detroit Department of Health, conducted the course with the assistance of Drs. Ray S. Dixon and Joseph A. Kasper, and Henry F. Vaughan, Dr.P.H., health commissioner of Detroit.

Society News.—Dr. Roseo G. Leland, Chicago, will address the Wayne County Medical Society, Detroit, October 15, on "Sickness Insurance Is Not the Remedy." A symposium on typhoid was conducted before the society, October 1, by Henry F. Vaughan, Dr.P.H., Dr. Joseph A. Kasper and Dr. Hugo A. Freund. —Dr. William H. Gordon, Detroit, recently addressed the Oakland County Medical Society on "Malignant Neutropenia, Its Etiology and Treatment." —A symposium on infantile paralysis was presented before the Livingston County Medical Society, September 7, by Drs. Clarence D. Barrett, Lansing, Raymond W. Waggoner and Clarence H. Snyder, Ann Arbor.

MISSOURI

Personal.—Dr. Frank M. Grogan, superintendent of the state hospital at St. Joseph, has been appointed to a similar position with the City Sanitarium, St. Louis, succeeding Dr. George A. Johns. The latter became superintendent of the St. Louis Training School, following the resignation of Dr. James Lewald, who plans to go to Laurel, Md. —Dr. Clifford L. Van Pelt, Paola, has been appointed health officer of Miami County, succeeding his father, the late Dr. Levi A. Van Pelt.

Society News.—Speakers before the St. Louis County Medical Society in Clayton, September 26, were Drs. James F. McFadden, on "Functional Nervous Diseases as Met in Daily Practice," and Joseph Hoy Sanford, "Urology and Its Relationship to the General Practitioner." —Speakers before the St. Louis Medical Society, September 25, were Drs. Quitman U. Newell, who presented "A Statistical Study of a Series of Corpus Uteri Carcinoma"; Samuel D. Katz, "Acute Intra-Abdominal Vascular Conditions," and Thomas K. Brown, "Puerperal Infection."

Candidates for Congress.—Dr. James A. Logan, Warsaw, secretary of the Benton County Medical Society, was selected as Republican nominee for Congress from the second congressional district, and Dr. William H. Breuer, St. James, was selected as nominee from the eighth district at a meeting of the district committee in Jefferson City, August 28.

Dr. Logan is mayor of Warsaw and has twice been a member of the state legislature from Benton County. Dr. Breuer is a past president of the Missouri State Medical Association, a councilor of the twenty-seventh district and a vice chairman of the council.

NEVADA

State Medical Meeting and Election.—The thirty-first annual session of the Nevada State Medical Association was held in Reno, September 21-22, with headquarters at the Hotel Golden. The program was as follows:

Dr. Miley B. Wesson, San Francisco, Urinary Calculi, Cause and Treatment.

Dr. Colin C. McRae, San Francisco, Treatment of Fractures of the Forearm.

Dr. George L. Stivers, Fall River, Mass., Types of Pleuropulmonary Adhesions.

Dr. William P. Lucas, San Francisco, Problems of Growth and Development During Childhood.

Dr. Richard O. Schofield, Boulder City, Industrial Work at Boulder Dam.

Dr. Lewis Michelson, San Francisco, Stricture of the Uterus in the Female: Its Diagnosis and Treatment.

Dr. William W. Washburn, San Francisco, Malignancies of the Gastro-Intestinal Tract.

Dr. George N. Hosford, San Francisco, Present Status of the Treatment of Strabismus.

Dr. Richard O. Schofield, Boulder City, was chosen president-elect and Dr. Edward E. Hamer, Carson City, was installed as president. Dr. Horace J. Brown, Reno, was reelected secretary and Elko was chosen as the place for the 1935 session.

NEW YORK

Society News.—Dr. Walter A. Reynolds, Albany, addressed the Medical Society of the County of Albany, September 26, on "Geriatrics." —Dr. Gerard H. Cox, Glen Cove, addressed the Medical Society of the County of Nassau, September 22, on "Correction of Facial Deformities by Plastic Surgery." —Dr. Lewellys F. Barker, Baltimore, addressed the Medical Society of the County of Monroe, Rochester, October 4, on "Contemporary Views of Angina Pectoris and Coronary Thrombosis." The society in cooperation with the Rochester Hospital Council has recently adopted regulations governing admissions to outpatient departments of hospitals. —Dr. Thomas Parran Jr., Albany, state health officer, was the guest speaker at the annual meeting of the Tuberculosis and Health Association of Rochester and Monroe County, September 26, on "Accomplishments and Possibilities in Conserving Health."

New York City

First Harvey Lecture.—Dr. William B. Castle, associate professor of medicine, Harvard University Medical School, Boston, will give the first lecture this season before the Harvey Society, October 18, at the New York Academy of Medicine, on "The Etiology of Pernicious and Related Macrocytic Anemias."

Schneller Returned to Prison.—Max R. Schneller, also known as Carl R. Elfes, who was sentenced last April to serve a year in New York County Penitentiary for illegal practice of medicine, was again in court, October 2, charged with escaping from prison. He was found guilty, sentence was suspended and he was returned to prison to serve out his original sentence. Schneller escaped from the prison on Riker's Island, July 23, and was found the next night in the Bronx. He spent the intervening time in the psychopathic ward of Bellevue Hospital, where physicians said he was suffering from hysteria, and in the Bronx County jail.

Personal.—Dr. William Salant, Cold Spring Station, has been elected guest professor of pharmacology at the New York Homeopathic Medical College and Flower Hospital. —Dr. G. Canby Robinson, who recently received a year's leave of absence as director of the New York Hospital-Cornell University Medical Center, has been appointed visiting professor of medicine at Peiping Union Medical College, Peiping, China. He will sail by way of Europe November 1. —Dr. Marie P. Levinson Warner presented a paper at the recent congress of the International Medical Women's Association in Stockholm on "The Status of Birth Control in the United States." —Dr. Samuel Silbert addressed the French Congress of Surgery, October 8-12, on "Surgery of the Adrenal Gland in Relation to the Treatment of Thrombo-Angiitis Obliterans."

NORTH DAKOTA

New Medical Board.—New members appointed to the North Dakota State Medical Board include Drs. John E. Hetherington, Grand Forks; Jesse W. Bowen, Dickinson, and William C. Fawcett, Starkweather.

OHIO

Society News.—Dr. Herrman L. Blumgart, Boston, addressed the Academy of Medicine of Cincinnati, October 8, on "Total Removal of the Thyroid."—Common infections of the eye, the skin and the genito-urinary tract were discussed by Drs. Arthur M. Culler, Elmer C. Loomis and Raymond E. Tyvand, respectively, at the first fall meeting of the Montgomery County Medical Society, Dayton, September 28.

Institute on Cardiovascular Disease.—The Heart Council of Greater Cincinnati and the Academy of Medicine of Cincinnati announce the second annual institute on cardiovascular disease under their joint auspices, to be held October 29. The opening session will be held at the Cincinnati General Hospital, where the medical, pediatric and pathology departments will present material dealing with different phases of circulatory disorder. Visiting guests and local physicians will conduct clinics and present cases at several other hospitals. At 4 o'clock in the afternoon a meeting of interested physicians will be called to consider organization of a regional heart association. In the evening the academy will present a symposium on cardiac pain, with Drs. Louis Hamman, Baltimore, and Walter W. Hamburger, Chicago, as speakers.

OREGON

State Medical Election.—Dr. George A. Massey, Klamath Falls, was named president-elect of the Oregon State Medical Society at the annual session in Corvallis, September 30. Dr. Albert M. Webster, Portland, was installed as president and other officers elected were Drs. Karl H. Martzloff, Portland, William J. Weese, Ontario, and R. Wayne Espersen, Bend, all vice presidents, and Blair Holcomb, Portland, secretary. The 1935 convention will be held in Gearhart.

PENNSYLVANIA

Society News.—Dr. Charles Geschickter, Baltimore, addressed the Dauphin County Medical Society, Harrisburg, October 9, on "Breast Tumors—Their Diagnosis, Treatment and Etiology in Relation to Ovarian Hormones."—Dr. Bernard P. Widmann, Philadelphia, addressed the Harrisburg Academy of Medicine, September 18, on "Evaluation of Treatment Procedure for Cancer with Special Reference to X-Ray and Radium."

Philadelphia

Society News.—Drs. Joseph V. Klauder and Lewis K. Ferguson addressed the Philadelphia Academy of Surgery, October 1, on "Erysiploid: Bacillus of Swine Erysipelas Infection—a Disease of Industry" and "Ambulatory Ligation in the Treatment of Varicose Veins," respectively.—A symposium on "Newer Concepts of Renal Physiology and Bright's Disease" was presented before the College of Physicians of Philadelphia, October 3, by Drs. Alfred N. Richards, Baldwin H. E. W. Lucke, Eugene M. Landis and Harold W. Jones.—Dr. Charles P. Noble, Radnor, among others, addressed the Obstetrical Society of Philadelphia, October 4, on "Dyspareunia: A Psychoneurosis."—Dr. Samuel R. Skillern Jr. was elected president of the Philadelphia Laryngological Society at the annual meeting in June, and Dr. Benjamin H. Shuster, secretary.

Saturday Morning Clinics Revived.—The Philadelphia General Hospital has inaugurated a series of clinics to be given by members of the staff on Saturday mornings from 11 to 1 o'clock. The clinics, which are a revival of a former custom, will be arranged and conducted in the interests of the general practitioner and will be open to the medical profession and medical students. They will cover a broad variety of medical and surgical subjects, with demonstration of cases, but not with operative clinics. At the first meeting, October 6, Drs. David Riesman and Thomas M. McMillan discussed "Recognition of the Failing Heart" and Dr. Edward A. Strecker, "The Neuroses as Encountered by the General Practitioner." The remaining programs for October are as follows:

October 13: Dr. James W. McConnell, Disturbances of Locomotion and Their Meanings; Dr. Arthur C. Morgan, Physical Signs of Pulmonary Tuberculosis.

October 20: Dr. Hubley R. Owen, Fractures of the Long Bones; Dr. Daniel J. McCarthy, The Cerebral Apoplexies.

October 27: Dr. Robert G. Torrey, Rheumatic Heart Disease; Dr. Earl D. Bond, Onset of Encephalitis in General Practice.

Dr. Russell S. Boles is chairman of the committee that has arranged the Saturday morning clinics.

Pittsburgh

Personal.—Philip B. Hadley, Ph.D., formerly associate professor of bacteriology, University of Michigan Medical School, Ann Arbor, and Arthur P. Locke, Ph.D., former chief of

biochemical research at St. Luke's Hospital, Chicago, have been appointed to the research staff of the Institute of Pathology of Western Pennsylvania Hospital. The institute is the medical research affiliate of the Mellon Institute for Industrial Research.

SOUTH CAROLINA

Personal.—Dr. William A. Carrigan, Conway, has been appointed health officer of Beaufort County.—Dr. Leonidas M. Stokes, Walterboro, has been appointed a member of the South Carolina Board of Medical Examiners to succeed Dr. Joseph T. Taylor, Adams Run, resigned.

Founders Day Celebration.—The Medical College of South Carolina, Charleston, will hold its first celebration of Founders Day, November 8. A program of clinics has been arranged for the day and in the evening a banquet will be held at which Dr. Stewart R. Roberts, Atlanta, will deliver an address on "Neurocirculatory Asthenia." The institution is 110 years old.

Society News.—Bruce Mayne of the U. S. Public Health Service addressed the Columbia Medical Society, August 13, on "Modern Views of the Economic Control of Malaria."—At a meeting of the Ridge Medical Society in Batesburg, August 20, Drs. Eddie H. Thomason and Leo F. Hall, State Park, presented papers on "Pneumothorax in Treatment of Tuberculosis" and "Childhood Type of Tuberculosis," respectively. Dr. William W. King, Batesburg, discussed "Dysentery, Bacillary and Amebic."

TEXAS

Personal.—Drs. James W. Bass, city health officer of Dallas, and Horace E. Duncan, health officer of Dallas County, were guests of honor at a dinner given by the Dallas Public Health Institute, September 11.

Society News.—Drs. Curtice Rosser and Samuel A. Shelburne will address the Dallas County Medical Society, October 25, on "Cancer of the Anal Canal" and "Etiology of Heart Disease in Texas," respectively.—Speakers at a meeting of the Nine Counties Medical Society (Medina-Uvalde-Maverick-Val Verde-Terrell-Edwards-Real-Kinney-Zavala counties) in Castroville, August 10, included Drs. Isaac Dudley Jackson, San Antonio, on "Treatment of Various Types of Malignancies"; Thomas M. Johnson, Del Rio, "The Doctor's View of Contraception," and William G. Brymer, Castroville, "Hydrochloric Acid Intravenously as a Therapeutic Measure."

WEST VIRGINIA

Society News.—Dr. William W. G. MacLachlan, Pittsburgh, addressed the Ohio County Medical Society, Wheeling, October 5, on "Experimental and Clinical Observations on Pneumococcal Pneumonia."—Dr. Paul Titus, Pittsburgh, addressed the Monongalia County Medical Society, Morgantown, September 4, on "Causes and Treatment of Sterility."—Drs. Virgil E. Holcombe and Walter W. Point, Charleston, were speakers at a meeting of the Kanawha Medical Society, September 11, on "Lesions of the Esophagus" and "Management of the Average Normal Obstetrical Delivery," respectively.—Dr. Royd R. Sayers, Washington, D. C., addressed the Fayette County Medical Society, Oak Hill, September 18, on industrial hygiene and sanitation. Members of the Kanawha and Raleigh County medical societies were guests.—Interns from three Huntington hospitals presented case reports at a meeting of the Cabell County Medical Society, September 13: Drs. Clarence H. Plymale, on "Acute Glossitis"; Charles F. Davis Jr., "Coronary Occlusion Without Pain," and Wilber V. Bradshaw, "Stab Wound of the Liver."

Wassermann Tests for Barbers and Beauticians.—A ruling which denied a license to any barber or beautician found to have a positive Wassermann test was recently modified by the State Committee of Barbers and Beauticians. The final decision was that any applicant found to have a positive reaction to the test may have forty-five days in which to take treatment. At the expiration of that time he or she may present to the state health commissioner a certificate from a licensed physician who is in good standing in his county or state medical society, stating that the applicant has been under active treatment during the forty-five-day period. The applicant must show that he is free from clinical signs of syphilis. The health commissioner may then issue a certificate of registration with the proviso that the applicant must file with the health commissioner every six months a certificate from a physician stating that he or she has been under the care or supervision of that physician during the period. Failure of

the applicant to carry out this provision shall result in the revoking of the certificate granted. When so revoked, it may be restored at the discretion of the committee.

GENERAL

Special Board Examinations.—The American Board of Otolaryngology will hold an examination in San Antonio, Texas, November 13, during the meeting of the Southern Medical Association. Sixty-two candidates were examined in Chicago, September 8, of whom thirteen failed or were conditioned. During 1935 the board will hold examinations in New York City during the annual session of the American Medical Association in June and in Cincinnati in the fall during the meeting of the American Academy of Ophthalmology and Otolaryngology.

Society News.—The Inter-State Postgraduate Medical Association of North America will hold its annual assembly in Philadelphia, November 5-9. —Dr. Louis E. Phaneuf, Boston, was chosen president-elect of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons at the annual meeting in White Sulphur Springs, W. Va., in September, and Dr. Marvin Pierce Rucker, Richmond, Va., became president. Dr. William H. Weir, Cleveland, was elected vice president and Dr. Arthur M. Meidenhall, Indianapolis, reelected secretary. Next year's meeting will be held in Skytop, Pa., September 16-18.

Ceremony in Jerusalem to be Broadcast.—A description of a ceremony in Jerusalem at which the cornerstone will be laid for the first medical center and graduate medical school in Palestine will be broadcast Tuesday, October 16, as a feature of the annual convention of Hadassah, the Women's Zionist Organization of America, in Washington, D. C. The new institution, which will be affiliated with the Hebrew University, will be built by Hadassah and the American Jewish Physicians Committee. On its staff will be a number of German scientists who have gone to Palestine to continue teaching and research.

Auxiliary Board Meeting.—Twenty members of the board of directors of the Woman's Auxiliary to the American Medical Association attended a meeting in Chicago, September 22. The revisions committee submitted a new constitution and by-laws which were approved unanimously. Members of this committee are Mrs. John A. McCaw, Denver, chairman, Mrs. T. Mitchell Burns, Denver, Mrs. J. Newton Hunsberger, Norristown, Pa., Mrs. William Wayne Babcock, Philadelphia, and Mrs. Arthur B. McGlothlin, St. Joseph, Mo. The Woman's Auxiliary to the Chicago Medical Society entertained the directors at luncheon.

Directory of Health Officers.—The U. S. Public Health Service has published a directory of the full time county health officers in the United States, compiled from data furnished by state health officers as of Jan. 1, 1934. The list contains more than 500 names of health officers of single counties and in addition shows a number of those in charge of units of two or three counties. Some states are organized on the district basis or with the town as a unit and in many cases the health officer's position is on a part time basis. Similar directories have been published annually since 1922, except for 1932, when funds were not available. The list appears in *Public Health Reports* for September 28, page 1134.

Association of American Medical Colleges.—The forty-fifth annual meeting of the Association of American Medical Colleges will be held in Nashville, Tenn., October 29-31, with headquarters at the Andrew Jackson Hotel. A symposium on graduate teaching will be presented by Drs. William McKim Marriott, St. Louis; Thomas Ordway, Albany, N. Y.; Willard C. Rappleye, New York; Frank R. Ober, Boston; John B. Youmans, Nashville, and Leroy E. Parkins, Boston. Among other speakers will be:

Dr. Ray Lyman Wilbur, Stanford University, Calif., Inspection of Medical Schools and Survey of Medical Education.

Dr. Charles C. Macklin, London, Ont., Relationship of Histology to Pathology.

Dr. John J. Mulowney, Nashville, Effect of the Depression on Medical Students of the Negro Group and on Internships Available.

Importations of Radium.—During the past ten years the United States has imported less than one third of a pound of radium, for which more than \$6,000,000 has been paid. Radium is one of the few commodities that has not been affected by economic conditions, according to the U. S. Department of Commerce. In fact, the heaviest importations have been made since 1929. Imports were fairly steady during the past ten years at from 125 to 170 grains valued at from \$400,000 to \$575,000 per annum until 1930. In that year the amount increased to 260 grains valued at \$925,000, the largest amount

ever imported in one year. In 1933, 179 grains valued at \$576,000 was imported at an average invoice price of \$3,217 per grain and during the first seven months of the current year \$400,000 worth was purchased abroad, it was stated. Most radium imports come from Belgium, which controls the world's principal supply in the Belgian Congo, but smaller consignments are received from Canada, where radium ore was discovered in 1930, and elsewhere.

Government Services

Bayer Company Ordered to Cease Unfair Competitive Practices

The Federal Trade Commission has issued an order to the Bayer Company, Inc., New York, to cease and desist from using unfair competitive practices in the sale of its acetylsalicylic acid tablets. The company is directed to cease using language in its printed advertising or radio broadcasting stating or giving the impression that "aspirin" is a trademark of the Bayer company. This order does not apply to advertising or packages to be sold in foreign countries in which the word "aspirin" has been held to be the Bayer Company's valid trademark. A list of seventeen representations are given in the commission's order, which the company is not to use unless properly qualified, limited or explained. Among them are such expressions as "It cannot harm the heart," "Bayer aspirin is always safe," "Take Bayer aspirin for any ache or pain, and take enough to end it. There is no harm in its free use," "Genuine Bayer Aspirin tablets promptly relieve headaches, neuritis, colds, toothache, neuralgia, sore throat, lumbago, rheumatism." The order is not to be construed, however, as preventing the company from making proper therapeutic claims or recommendations based on reputable medical opinion or pharmaceutical literature, it was stated. The third prohibition in the order is one providing that the company shall not in any way represent that acetylsalicylic acid tablets manufactured by other firms are counterfeit or spurious. The company waived a hearing and did not contest the proceeding of the commission.

Medical Research Correlating Bureau—A Warning

Recently a number of complaints have been received by the Army Medical Library directly or indirectly concerning the "Medical Research Correlating Bureau of Washington, D. C." A copy of a receipt for \$10 from a Mr. J. J. Sharkey, representative of this "Bureau," has been sent to the Library. He states in effect that for \$30 the "Bureau" will furnish "routine evaluated reports" secured by and through the "facilities of the Surgeon General's Library," currently by mail and later the same in printed form with a suitable binder. The complaints are that money has been accepted by this representative and nothing sent in return and letters not answered.

From time to time in the past complaints of this nature have been made to the Army Medical Library regarding various unofficial "services," which are supposed to furnish certain abstracts, answer enquiries and otherwise serve their subscribers. It should be obvious that such "bureaus" and individuals in no way represent the Army Medical Library. The Library is a national institution and its collections are available to those who come to its reading rooms and through the inter-library loan system to physicians, dentists, veterinarians and others throughout the country. Persons who abstract the medical literature for a fee are as much entitled to use the library as others. The Library, however, objects to the implication that any "bureau" or other unofficial organization or individual has access to material in the Library that is not open to all readers. Usually such organizations and individuals are careful not to make the direct statement that such is the case, but they at times imply as much.

The Library, except for the letters of complaint above mentioned, has never heard of the "Medical Correlating Bureau" nor of the individual acting as its representative.

CORRECTION

The Agglomerular Kidney.—In an editorial with this title, THE JOURNAL, Sept. 22, 1934, page 922, the statement "within sixty days after partial urethral obstruction plus unilateral exposure to x-rays" should be changed to read "within sixty days after partial ureteral obstruction or unilateral exposure to x-rays."

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 14, 1934.

The British Association for the Advancement of Science

At the annual meeting of the British Association for the Advancement of Science, held at Aberdeen, a number of subjects of interest especially to physicians were discussed.

THE MECHANISM OF COLOR SENSATION: COLOR BLINDNESS

In the Section of Physiology, the president, Dr. H. E. Roaf, professor of physiology in the University of Liverpool, devoted his address to a new view of color sensation. His tentative conclusion was that to explain the phenomena of color vision three groups of nerve fibers passing to the brain must be assumed. Helmholtz had suggested that the differentiation is due to three photo-active substances acted on by the long, medium and short wavelengths of the spectrum, respectively. The ranges of radiation which affected these three substances overlapped so that, for example, some rays affected all three. But there was no evidence of the presence of three photo-active substances, only one (rhodopsin or visual purple) having been found. Moreover, in order to explain color blindness it had to be assumed that one photo-active substance was not absent but that the range of activity was shifted, so that the one substance was activated by the range which was formerly active on two substances. It did not seem likely that such a transformation would occur. The president thought that "normal vision might be due to a receptor which gave rise to a red sensation, one which gave rise to a blue sensation, and one which gave rise to a not-blue, not-red sensation, which of course corresponded to green. The wavelengths that stimulated the several receptors were not known. The real difference between the various hypotheses was the extent and region of the spectrum which stimulated the end organs."

A NEW TEST FOR THE WATERING OF MILK

At a joint meeting of the chemistry and agriculture sections, Dr. J. F. Tocher criticized the freezing point test now used to detect the watering of milk, for which the claim is made that it can detect 5 per cent of watering. Dr. Tocher thought that this test was too unreliable to be the basis of convictions for adulteration. There was no standard for the freezing point of milk, and analytic authorities were not yet agreed as to the nearest approach to the freezing point of water that occurred in genuine samples of milk. Dr. Tocher brought forward his "constituents test," which is based on his discovery that, when solids-not-fat percentages are high, the proportions of the individual constituents differ from the relative percentages in the cases in which the solids-not-fat percentages are low. Therefore rich milk when watered will show on an average different proportions of the constituents from those of poor milk. The problem is one of probability. On the basis of analyses of 474 samples of milk from individual cows, he solved an equation that gave the relations of the four chief constituents to the total solids other than butter fat. The predicted solids were found to approximate closely to the actual solids in samples from individual cows. But when a sample was watered the predicted values differed significantly from the actual values. Reverting to the freezing point test, Dr. Tocher was grieved that judges were misled by witnesses who failed to recognize their responsibilities and the gravity of statements that the accused, if innocent, were not in a position to rebut.

DIET AND DENTAL DISEASE

Mrs. May Mellanby gave some interesting applications of her doctrine of the importance of diet in the prevention of dental disease. She said that in spite of the excellent work of dentists there was more dental decay than ever in the world. Sad to relate, educated people suffered more than natives living their primitive life. But when such natives came into contact with civilization their teeth began to suffer. The Eskimos had beautiful teeth—only 3 per cent were said to suffer. The primitive Negro of the tropics had white pearly teeth free from decay, but his descendants in the United States were almost as prone to dental disease as Europeans. Mrs. Mellanby said that wrong diet (mainly deficiency of vitamin D) and lack of sunshine especially in early life were the primary causes of caries and pyorrhea. Cereals, including oatmeal and maize, were harmful and anticalcifying foods. The Eskimo had good teeth because in his natural condition he hardly ate cereals and his diet was rich in animal fat, with which vitamin D was associated. It was true that the diet of natives in tropical countries included much cereal, but most of, if not all, their skin was exposed to the sun's rays and the necessary vitamin was synthesized in their bodies. Dental decay was prevalent in countries such as England because cereals were the cheapest food, there was little sunshine, and what there was was not allowed to play on either the body or the food.

Crossing Places for Pedestrians

The latest measure for the prevention of road casualties—the provision of marked crossing places for pedestrians—has been highly successful. It is not an absolute safeguard, for persons have already been killed at these safety lanes. But an accident at them greatly increases the responsibility of the motorist. Pedestrians can signal that they are about to cross, and it is the duty of the motorist to slow down at every crossing and exercise every care. In case of an accident it is no excuse for him to say that he did not see the pedestrian step off the sidewalk. If pedestrians cross at these appointed places they have the law behind them. It is proposed to warn them that if they cross at other places they do so at their own peril. These crossings are not equipped with automatic signals nor are they under the control of traffic officers. Crossings of the latter type have for some time been in existence at important road junctions.

The British Medical Association in Conflict with a Scheme of Contract Practice

A long-standing dispute exists in South Wales between the Caermarthenshire physicians and a local workmen's medical committee. It affects 18,000 workers and their dependents, and it originated in an attempt to reduce the subscription rates that had existed for some time. These were 40 cents per month for men with dependents and 20 cents for men without them. The workmen's committee intimated that it was dissatisfied with the services rendered and proposed that the rates be reduced to 32 and 12 cents respectively. At the same time, the rates of subscription by the workers would be maintained at the same level and the saving be used for supplying an ancillary specialist service, for which the staff would be recruited by the committee. Thus conflict with the local medical profession arose as to the terms of remuneration and the appropriate method for providing an ancillary specialist service. The existing contract was terminated. The physicians brought forward a scheme of their own for a public medical service, both general practitioner and specialist, at rates graded to suit the varying income of different classes. This scheme is on lines approved by the British Medical Association. The workmen's committee made the countermove of introducing into the area three physicians to do the work on a

salaried basis. But they are meeting with difficulties. One of the physicians, a member of the British Medical Association, soon resigned. Two specialists, previously under contract with the committee, also resigned. The British Medical Association holds that the counterstroke of the committee militates against the interests of the patients and professional tradition. It is not a far step from this system to the employment of salaried whole time physicians by the state for domiciliary treatment, which the association has always opposed. Also, a lay body is not fully equipped for the selection of a staff for the medical service. The workers are reminded of what happens when they quarrel with their employer and he seeks to introduce other workers to replace them. The association is not a trade union but it will support the professional well being of its members. The dispute was the subject of a report by the council to the representative body at the recent annual meeting of the association, when Sir Ewen MacLean said that if the association failed in this area it would be faced with a situation that would imperil the medical services in the industrial areas of South Wales.

Women in Medicine in Great Britain

The present position of women in medicine in Great Britain is shown in the educational number of the *British Medical Journal*. Coeducation is the general rule outside London, where the only schools open to women are the London School of Medicine for Women (which is confined to them) and, to a limited extent, University College Hospital and King's College Hospital. The total number of women medical and dental students in the medical schools of Great Britain in the session 1931-1932 was 1,272, while the corresponding number for males was 9,107. The London School of Medicine for Women (Royal Free Hospital) was established for the training of women in medicine in the days before there were any coeducational facilities for them, and it is still the principal school. Arrangements are made for the students of the school to obtain clinical instruction in special subjects at the National Hospital for Nervous Diseases, the Royal London Ophthalmic Hospital, the Great Ormond Street Hospital for Children, the Elizabeth Garrett Anderson Hospital, the South London Hospital for Women, the Cancer Hospital and the Central London Ophthalmic Hospital. The London School of Medicine is of great importance to medical women. All its postgraduate appointments are open to women as well as to men. There is a gynecologic unit under a woman professor, entirely staffed by medical women. There are now more than 5,000 women in the Medical Register. There is an increasing demand for the services of women physicians, and the proportion of them who make good is as high as that of their male colleagues, if not somewhat higher. In the municipal hospitals a number of new resident appointments to be held by medical women have been created, for which the supply is not equal to the demand. The number of women doing specialist and consulting work is rapidly increasing. In the large cities there are hospitals staffed entirely by women doing excellent work.

Records of Centenarians

As skepticism has been expressed with regard to the existence of centenarians, the following, taken from the *Times* of September 4, should be of interest: Mrs. Palmer of Ulundi Road, Blackheath, London, will celebrate her 107th birthday today, when she hopes to entertain some members of her family. She will have a birthday cake bearing 107 candles, presented by an old friend. Yesterday she gave a party to a number of intimate friends. Her mental faculties are still good and she takes a keen interest in her home. She looks with pride on a portrait of herself painted on the occasion of her 100th birthday, when she received a telegram of congratulation from the king.

Mrs. Elizabeth Miller of Murthly, Perthshire, celebrates her 104th birthday today. When she was born in 1830 a holly tree was planted in front of her home beside the river Tay. She still lives there and the holly tree flourishes.

Mrs. Caroline Merriott, an inmate of the Mayday Hospital, Thornton Heath (near London), will be 109 at the end of this month. It is noteworthy that all these centenarians are women, which is in keeping with the general rule of the greater longevity of women than of men.

Congress of French-Speaking Pediatricians

The seventh congress of French-speaking pediatricians was held in Paris, under the chairmanship of Professor Ombrédanne. Scientists from Belgium, Ireland, Italy, Switzerland, Uruguay and other countries participated. In his address the president, who is a surgeon, called attention to the important rôle of operative procedures in infantile therapeutics; for example, in pyloric stenosis and disorders of the parathyroids. The pediatricians of the future will be worked out through close collaboration of physicians and surgeons. Three well defined topics constituted the agenda:

INFLUENCE OF CLIMATE ON THE DISEASES OF CHILDREN

Prof. Georges Monrquand of Lyons considered in his paper the medical repercussions associated with changes in the weather. He discussed the symptoms of "heat stroke" and "cold stroke," or chill, both of which are grave manifestations in children, because their heat-regulatory functions are insufficiently developed. He called attention to the effects of the overheated air of nurseries, cubicles and incubators, and of too much clothing. He reviewed the symptoms associated with barometric changes, changes in the intensity of the solar rays, changes in the electrical tension of the atmosphere, and complex changes in the weather (symptoms due to south winds, east winds, west winds and stormy weather). Some persons show a peculiar sensitiveness and even have "premonitions" in advance of other persons. These reactions include the simple irritative type, accompanied by nervousness and insomnia; the thermic type, and the grave type with dehydration. In "weather-sensitive" children the reactions are varied, the following manifestations having been observed: irritability, inattention, urticaria, pruritus, asthenia, insomnia, and respiratory disturbances. Then there are the symptoms associated with a change of climate, occurring in children transported from their customary milieu. Monrquand divides children into two classes, the "meteorosensitive" and the "meteororesistant," the former presenting a morbid state unsuitable to resistance (disturbances of the vagosympathetic system, hepatic involvement, endocrine insufficiency, tendency to colloïdoelastic reactions and to humoral flocculation). Meteoropathology is a recent science, but many facts that cannot be explained by ordinary pathology may some day be understood through the applications of meteoropathology. P. F. Armand Delille of Paris developed the same theme, discussing morbid constitutions as a result of which some children are sensitive to climatic changes: lymphatism, state of the rhinopharynx, vagosympathetic disequilibrium, sequels of previous infections, avitaminosis. He considered the effects of seaside and mountain climate. P. Woringer of Strasbourg read a paper on the influence of the seasons on the evolution of disease. He described the method for correctly establishing seasonal curves in their relations to medical statistics. These curves present nearly always an annual maximum and minimum, separated by an interval of six months. Measles occurs mainly between March and July, scarlet fever between January and

March, diphtheria between November and January, and epidemic meningitis and epidemic (lethargic) encephalitis between December and July, with the peak in March. Whooping cough and influenza may appear at any season. Rickets is most common during the months having the least sunshine. Woringer gave as an explanation for the seasonal nature of various epidemics the habitual alimentary regimen, and the phases of exaltation and depression in the functioning of the organs themselves. He endorses the hypothesis of Moro with regard to the hormonal crisis of springtime, the changes in the sun's rays, the temperature, the hygrometric condition of the air, and finally the common direction of the regional winds. The general discussion was participated in by Jaubert of Hyères, Gauthier of Geneva, Lereboullet of Paris, de Chabanolle of Chamonix, Bauza of Montevideo, Pechère of Brussels, Cathala and Marfan. Many further communications were presented.

RÔLE OF THE FILTRABLE TUBERCULOUS VIRUS IN PEDIATRICS

In their paper, Paiseau and Valtis defined a filtrable tuberculous virus and described the methods that enable one to observe its effects on experimental animals. They concluded that the technic of the diagnosis of tuberculosis by inoculation in the guinea-pig should be revised, for one is not justified in concluding that tuberculosis is not present because such inoculation is not followed by the appearance of the ordinary signs of the disease. Several unofficial communications followed this presentation.

OMPHALOMESENTERIC VESTIGES IN THE CHILD

The third topic, "Pathology of the Omphalomesenteric Vestiges in the Child," was discussed by Fèvre and Semclaigne of Paris. The accidents due to Meckel's diverticulum are not so rare as is supposed. Sixteen cases were observed in six years in the department of Professor Ombrédanne, and an operation was performed in twelve of the cases by one of the speakers. One finds Meckel's diverticulum six times more often in boys than in girls; it sometimes opens into the umbilical vesicle and sometimes into the intestine and sometimes is closed at both ends and forms a cyst. The paper gave a survey of the possible accidents, including ulcer of Meckel's diverticulum, hernia, cysts, intestinal perforations and peritonitis. The treatment is always operative. During the discussion, Mr. Perrot of Geneva stated that he had observed within two years five cases of lesions of Meckel's diverticulum.

Meeting of German Psychiatrists

At the recent annual session of the Deutscher Verein für Psychiatrie, in Münster, there was an extensive discussion on the practical application of the law for the prevention of posterity with hereditary defects. In his paper on "Clinical Psychiatry and Eugenics," the Munich psychiatrist Bumke pointed out that, among the methods for the prevention of posterity with hereditary defects, birth control must be absolutely rejected, since such methods, in view of the existing reduced birth rate, would be adopted chiefly in circles that are essentially eugenically sound and would thus bring about a further reduction in the birth rate. Also, if interruption of pregnancy on eugenic grounds should be permitted, the danger of abuses would be great. Bumke is of the opinion that by wisely directed sterilization of weakminded persons a rapid elimination of these strains can be obtained. However, with schizophrenia, by reason of its unfavorable hereditary prognosis, its recessive character and its transmission by phenotypically sound intermediate progenitors, a rapid improvement cannot be

expected. With regard to epilepsy, it appears necessary to sterilize every person whose condition cannot be shown to be due to exogenous causes. In manic-depressive insanity the law should be applied only to patients with pronounced symptoms and not to persons with mild depressive tendencies, as the latter may be valuable members of society. In the case of severe chronic alcoholism the hereditary predisposition is of such a dominant nature that, from the eugenic point of view, offspring are not desirable. These pronouncements were supplemented by a paper of Rüdin of Munich on "Psychiatry and Eugenics," which dealt with eugenic selection. A further need is the establishment of a graduated scale of the best and of the worst families, from the hereditary point of view.

Among some interesting facts reported in various papers, Geyer of Kiel found that in 80 per cent of his imbecile patients the condition could be traced to endogenous causes, whereas the idiots were mostly of exogenous origin. Pohlisch of Berlin found in 395 offspring of 3,500 morphine addicts no evidence of the existence of germinal damage. On the other hand, the children of women addicted to morphine showed serious evidence of withdrawal injuries, from which many of them died.

Pönitz of Halle brought out that encephalography applied to patients with dementia paralytica will reveal to a certain extent what success may be expected from malaria treatment.

A paper by Kretschmer of Marburg dealt with the "Development of Personality in Psychotherapy," which was supplemented by further papers on "Responsibility in Hospitals" and on the "Present Situation in Psychotherapy." Other papers brought out that, because of the increased abuses of hypnotics sold over the counter without a prescription, restrictive legislative measures will doubtless soon be enacted.

Berlin's "Biologic Group" of Physicians

Under the new government the nature cure movement and, in general, the so-called biologic methods have received far-reaching encouragement. A pronouncement of Professor Reiter, the head of the federal bureau of health, reads "The reich will not rear medical men but physicians who can think biologically." But there can be no objection to this statement, since it is entirely in line with the principles of scientific medicine. Recently a so-called biologic group of physicians, which has organized evening discussions for physicians, was created in Berlin. On the first evening set apart for such discussions, Professor Jansen, who has been appointed to the newly created chair for "nature cure and natural mode of living," spoke on the general aspects of his assignment. He emphasized that the chief task and duty of the physician is to prevent disease—by medical advice so to organize the mode of living of the German people that the predisposition to disease shall disappear. In order to bring this about, one of the chief things necessary is to familiarize physicians with the newer knowledge of nutrition and the health-promoting factors light, air, sunshine, water and the like. As compared with the paramount importance of these primary factors, the petty controversies concerning methods are insignificant. The genuine physician should be able to offer solutions also for psychic problems. He should become again a real family adviser—not only in times of sickness but also in days of health. Serving in the capacity of a new type of priest-physician, the people must be led away from the worship of "progress" back to a solid but quiet fulcrum. While disclaiming any desire to belittle the accomplishments of the present epoch, it must be insisted that mankind shall again become the pivot about which all technical discoveries must turn instead of expecting man to revolve about the inventions and discoveries of science like insects about a light. Jansen stated that it was not his aim to create hospitals with never so modern and never so hygienic equipment and arrange-

ments. His goal was an immense "house of health" in the heart of Berlin, where hundreds of thousands of compatriots might become familiar with wholesome food and the value of a life spent in the open, with a maximum of fresh air and sunshine. The "lost connection" between the people and the universities might thus be reestablished. Through such an institution the key to true healing of disease would be found, and in an atmosphere of positive psychic influence, and through the utilization of biologic therapeutic methods, it would be most feasible to bring back health to the whole German people.

On the second evening Dr. Bastanier, instructor in homeopathy at the University of Berlin, spoke on the "Problems of Homeopathy." On the third evening the topic will be "Treatment with Leeches," and on the fourth evening "Nasal Reflex Therapy." On these two evenings not only representatives of well known "schools" will speak but also a number of trail-blazing individualists.

Statistics on Prussian Hospitals

The Prussian bureau of statistics has published a report on the activities of Prussian hospitals during the period from 1879 to 1929, which furnishes evidence of the prodigious development of hospital services. The number of general hospitals rose in this period from 998 to 2,320, and the number of beds increased from 42,497 to 251,545, or from 15.8 to 64 to 10,000 inhabitants. In 1929, 2,470,595 persons received treatment, and the total number of days of hospitalization was 67,500,000, which denoted an eightfold increase over the year 1879. The unprecedented development of the *kranken-kassen*, or health insurance societies (membership in 1885, 2,200,000, and in 1929, 11,700,000), has obviously contributed no small part to the development of the hospitals. In 1879 the average stay in a hospital was 31.6 days, and in 1929 it had dropped to 27.4 days. In 1879 there were 1,360 physicians and 4,728 nurses actively engaged in the hospitals; in 1929 their numbers had risen to 8,533 and 39,958, respectively. Of the diseases treated in the hospitals it may be mentioned as an example that 30,650 persons with tuberculosis were treated during the period 1877-1879, while 419,417 persons were under treatment for that disease in 1929.

Involvement of the Hypophysis in Eclampsia

The hypophysis is commonly assumed to play a part in the origin of eclampsia. Not all manifestations, however, as Bickenbach in a recent address before the Göttingen Medical Society pointed out, can be traced to the unassisted action of the posterior lobe of the hypophysis. Particularly with respect to glomerulosis and the liver changes, doubtless other influences besides the action of the posterior lobe play a part. A discrepancy lies in the fact that the secretion of the posterior lobe induces an excretion of chlorine, whereas in pregnancy and in eclampsia there is a retention of chlorine. In rabbits no difference between the gravid state and the nongravid state, with reference to the excretion of chlorine, was found as a result of the influence of the hormone of the posterior lobe. In the woman in an advanced state of pregnancy, the total excretion of chlorine following injection of posterior lobe is diminished as compared with the results under the same conditions without hypophysis. Tests were likewise instituted to discover to what extent the blood serum is capable of counteracting the antidiuretic and chlorine-evacuating influence of the hormone. It was found that the blood can, for the most part, nullify the action of the hormone; there is, however, no marked difference between the serum of gravidas, nongravidas and preeclamptic subjects. These researches would indicate, therefore, that the hormone theory alone does not suffice to explain the genesis of eclampsia.

Doctors for Villages

A donation of 6,000,000 yen has recently been contributed by Mitsubishi, the most famous millionaire here, for social welfare work. One million yen is to be spent to establish medical facilities in villages where there have not been any. The number of such villages is reported officially to amount to 3,527 throughout the country. But about 1,000 villages are reported to be in urgent need of medical facilities. The government is busy preparing to appoint the official doctors within the year in about 500 villages. The building of the clinic or offices, costing each about 2,000 yen, will be begun before long under the superintendence of the local government. By 1936, 1,000 doctors will be appointed to these remote villages. As a rule, there will be no medical fee in case of poor farmers and fishermen, but for well-to-do people there will be a small fee, which is expected to be paid chiefly by the annual relief fund or from special grants made by the emperor yearly.

Regulations for Prevention of Accidents

The home office has drawn up regulations concerning the prevention of accidents and for safety in workshops and places engaged in all major industries other than factories and mines, which are already covered by the factory law, the regulations concerning accident prevention and hygiene in factories, the regulations concerning dormitories attached to factories, the mining law, and the regulations concerning work and relief of miners. The regulations concerning safety and hygiene in places of quarrying or digging or extracting stone, gravel, sand or soil from the earth came into force June 1. The regulations provide facilities and equipment concerning prevention of accidents and hygiene in workshops. They are as follows:

1. Selection and appointment of supervisors to take charge of matters concerning prevention of accidents and hygiene.
2. Provision of safety passages, safety facilities and equipment in shafts, passages and ladders underground.
3. Facilities and equipment in open mines.
4. Measures for the prevention of falling bodies.
5. Safety facilities in transportation by vehicles on rails.
6. Safety devices for winches.
7. Care in handling gunpowder and other explosives.
8. Facilities to prevent workers in dangerous places from falling.
9. Prevention of dust.

Opticians and Ophthalmoscopy

It is said that 40 per cent of the school children and more than half of the adults are affected with subnormal sight. Ophthalmoscopy, naturally, is demanded on all sides. The opticians in the greater cities and towns have of late established a dark room for the examination of the eyes. When the examiners are the clerks, the examination is usually free. When qualified doctors do this work, some charge but others require no fee. At present there are few who go to the doctor for the examination, but many go to the optician's to have an examination free of charge. Therefore, whether ophthalmoscopy is practicing medicine or not has come to be discussed loudly. The opticians and those who work in the shops have petitioned the government to the effect that a license should be granted to them in recognition of their experience or the license should be granted through some kind of examination. They want the title "ophthalmometrist" independent of the doctors. The Japan Ophthalmologic Association has also made a representation to the government in opposition to the opticians' petition. Sooner or later, the ophthalmometrist probably will be licensed, as the public need for more refraction tests is urgent.

Subnormal School Children

The department of physical education of Tokyo has reported a recent investigation of the weak boys and girls in 541 primary schools containing 694,147 children in which methods differing from any previous investigation were used. The department asked the teachers to report the number of boys and girls whom they thought to be too weak, physically or mentally, to be among the normal boys or girls. Formerly this was usually done by means of physical or mental examination by specialists. The following seven items were reported on by the teachers: (1) inferior mental power; (2) feeble-mindedness; (3) reduced hearing; (4) weak sight; (5) stammering; (6) sickness; (7) deformity. A comparatively small number was so reported. The criteria were whether weak boys or girls should be specially educated. The numbers were as follows: (1) 7,783, (2) 7,206, (3) 1,023, (4) 2,020, (5) 2,880, (6) 3,841, (7) 1,865. Special classes for such children are as yet insufficient but the authorities are making a great effort to establish special schools.

Increase in Suicide

In the Tokyo Prefecture 1,805 persons committed suicide in 1933 and 2,000 attempted suicide, while 1,585 committed suicide in 1932 and 1,048 attempted suicide. When in 1922 the population of this prefecture was 3,790,000, the suicides numbered 916 and attempted suicides 453. Ten years after this, in 1932, the population was 5,870,000. The causes were sickness 20 per cent, poverty and unemployment 13 per cent, and family trouble and disappointment in love 9 per cent. The favorite place for committing suicide is the crater of the volcano Miharayama on a small island near the bay of Tokyo, where 125 suicides occurred during 1933 and 826 attempted suicides. It has long been believed in this country that suicide for a cause is noble, and few think it is wrong to kill oneself. The government and the private social welfare agencies have joined in providing medical care for the distressed.

Current Medical Literature

The *Japan Medical World*, a weekly journal, whose proprietor is Dr. S. Tsuchiya, a member of parliament, will add to every issue more than four pages of all the Japanese medical literature written in foreign languages. This material will be abstracted from about forty medical journals in this country and will be sent to all the important universities, laboratories, manufacturers, scholars and publishers all over the world from July this year.

Dr. Rudolph Bolling Teusler

Dr. Rudolph Bolling Teusler, director of St. Luke's Medical Center, died August 10 at St. Luke's Hospital. He had been suffering from heart disease for four years. At the earnest request of his family and friends, he went to Arizona last September to recover his health. He returned to Japan last July. It is believed that he worked too hard here for the institution to which he had devoted thirty-four years of his life. In recognition of his merits, he was decorated with the fifth class Order of the Rising Sun. The completion of the new St. Luke's Hospital last year crowned his career as medical missionary in Japan. Acknowledged as the best in the Orient, the institution is an impressive example of the work of American Christian philanthropy. He was born at Rome, Ga., Feb. 25, 1878. He was graduated with the degree of Doctor of Medicine from the medical college of Virginia in 1894, where from 1896 to 1900 he was assistant professor of pathology and bacteriology. He came to Japan in 1900. He was once physician to the British embassy and later was a member of a commission to provide postgraduate medical training in the United States for Japanese students. He did valuable work with the Red Cross in the Allied expedition to Siberia. He began working in 1903 on the institution that was to become the St. Luke's International Medical Center of today.

Marriages

CLAIRE M. DIXON, Ina, Ill., to Miss Lucile Montane of Sacramento, Calif., in East St. Louis, Ill., September 8.

WILLIAM DORUS STUBENBORD, New York, to Miss Jean Cardiff Tennant of Jersey City, N. J., June 16.

EUGENE LA FORREST SWAN, Brooklyn, to Miss Elizabeth Farwell Mann of Waltham, Mass., August 31.

CYRIL FANTUS SHERMAN, Danville, Ill., to Miss Jennie Eylene Worden of Hillsboro, Wis., May 27.

LEWIS MONROE SMITH, Atlanta, Ga., to Miss Edna Louise Mabee of Saratoga Springs, N. Y., June 2.

BENJAMIN MARVIN HAND to Miss Adelaid A. Hancock, both of Philadelphia, June 9.

VERNON SHELTON DICK to Miss Blossom Bacon, both of Ann Arbor, Mich., Sept. 5.

EDWARD L. SPANGLER, Ouray, Colo., to Miss Mabel Sanders of Chicago, May 19.

IRVING SCHOENFELD to Miss Ruth Levy, both of New York, June 14.

Deaths

Thomas Edward Satterthwaite, New York; College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1867; member of the Medical Society of the State of New York; a founder and fellow of the American College of Physicians; served in the Franco-Prussian War; one of the founders, and at one time secretary, vice president, professor of pathologic anatomy and general medicine, Post Graduate Medical School; lecturer on comparative pathology, Columbia Veterinary College, 1881-1882; organized the medical and surgical staff of the Chambers Street House of Relief, now the Hudson Street Hospital, in 1875; a founder and president, 1894-1899, of the Babies' Hospital; microscopist and later pathologist at St. Luke's Hospital, 1872-1882; pathologist to the Presbyterian Hospital, 1873-1888; consulting physician to the Post-Graduate, Orthopedic and Manhattan State hospitals; served as a first lieutenant in the U. S. Army Reserve Corps, 1911-1917; author of "Manual of Histology," "Practical Bacteriology," "Diseases of the Heart and Aorta," "Cardio-Vascular Diseases," and "Diseases of the Heart and Blood Vessels" and many other works; aged 91; died, September 19, of senility.

Frank Tryon Stevens ☉ Colorado Springs, Colo.; Northwestern University Medical School, Chicago, 1893; member of the American Psychiatric Association, Association for Research in Nervous and Mental Diseases and the Central Neuropsychiatric Association; past president of the El Paso County Medical Society; on the staffs of the Mount Pleasant (Iowa) State Hospital, 1896-1912, and the Milwaukee Sanitarium, Wauwatosa, 1912-1913; on the staffs of the Union Printers' Home and Tuberculosis Sanatorium, Glockner Hospital, Bethel Hospital and St. Francis Hospital; aged 67; died, September 6, of arteriosclerosis and cerebral hemorrhage.

William Palm, Brazil, Ind.; Medical College of Indiana, Indianapolis, 1905; member of the Indiana State Medical Association; at one time secretary of the Clay County Medical Society; served during the World War; county health officer; formerly coroner and jail physician; on the staff of the Clay County Hospital; aged 51; died, September 10, at his home in Harmony, of heart disease.

John Henry Kuser ☉ San Rafael, Calif.; Universität München Medizinische Fakultät, Munich, Bavaria, Germany, 1885; past president and secretary of the Marin County Medical Society; formerly on the staff of the San Rafael Cottage Hospital; aged 71; died, August 27, of acute hepatitis, atrophic cirrhosis of the liver and arteriosclerosis.

Marcus Fitzherbert Wheatland ☉ Newport, R. I.; Howard University School of Medicine, Washington, D. C., 1895; member of the New England Roentgen Ray Society; formerly trustee to the Howard University, Washington, D. C.; visiting physician to the Newport Hospital; aged 66; died, August 16, of diabetes mellitus and bronchopneumonia.

Abram Barnes Hooe, Washington, D. C.; Columbian University Medical Department, Washington, 1896; member of the Medical Society of the District of Columbia; fellow of the American College of Surgeons; served during the World War; aged 63; died, September 19, in the Walter Reed General Hospital, of carcinoma of the ileum.

Alexander W. Acheson, Denison, Texas; University of Pennsylvania School of Medicine, Philadelphia, 1867; member of the State Medical Association of Texas; past president and secretary of the Grayson County Medical Society; on the staff of the Denison City Hospital; aged 91; died, September 7, of myocarditis and chronic nephritis.

Alden Blodgett MacDonald, Warren, Pa.; Jefferson Medical College of Philadelphia, 1904; member of the Medical Society of the State of Pennsylvania; president of the Warren County Medical Society; on the staffs of the Warren General and Warren State hospitals; aged 54; died, August 16, of carcinoma of the liver.

George Willard Mehl, Ashland, Ohio; Ohio Medical University, Columbus, 1904; member of the Ohio State Medical Association; veteran of the Spanish-American War; formerly county health officer; on the staff of the Samaritan Hospital; aged 68; died, August 29, of myocarditis and chronic interstitial nephritis.

Martyn David Sheehan @ Stoneham, Mass. (licensed in Massachusetts in 1895); member of the New England Obstetrical and Gynecological Society; member of the board of health; aged 63; on the staff of the Winchester (Mass.) Hospital, where he died, September 4, as the result of an automobile accident.

Russell Edward Titman @ East Orange, N. J.; New York Homeopathic Medical College and Flower Hospital, 1912; on the staff of the Montclair (N. J.) Community Hospital; aged 44; died suddenly, September 8, in the Mountainside Hospital, Montclair, of sciatica, anaphylaxis and pulmonary edema.

Eudora Pierce Higgins Chismán, Boston; Woman's Medical College of the New York Infirmary for Women and Children, 1894; an affiliate Fellow of the American Medical Association; aged 70; died, August 22, in the Palmer Memorial Hospital, following an operation for removal of the gallbladder.

James Joseph La Salle, Phoenix, Ariz.; University of Michigan Medical School, Ann Arbor, 1896; member of the American Laryngological, Rhinological and Otological Society; formerly health officer of Toledo, Ohio; aged 59; died, July 22, of malignancy of the left brachial plexus.

Gerald Stinson Glasco, Hamilton, Ont., Canada; University of Toronto Faculty of Medicine, 1893; member of the American Psychiatric Association; member of the local lunacy commission and director of the mental hygiene clinic of the board of health; aged 62; died, July 22.

Wesley Johnson Barrett @ Camden, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1901; fellow of the American College of Surgeons; surgeon to the West Jersey Homeopathic Hospital; aged 60; died, September 13, in Haddonfield, of cerebral hemorrhage.

Jay Clarence Knipe @ Philadelphia; Jefferson Medical College of Philadelphia, 1890; associate professor of ophthalmology at his alma mater; on the staffs of the Jefferson, Jewish and Mary J. Drexel hospitals; aged 65; died, September 2, of coronary thrombosis.

Edwin Woodbridge Morse, Portland, Ore.; Jefferson Medical College of Philadelphia, 1908; member of the Oregon State Medical Society; served during the World War; aged 58; died, August 22, in San Francisco, of carcinoma of the prostate and uremia.

Jay Hathaway Utley, Beverly Hills, Calif.; Bellevue Hospital Medical College, New York, 1883; member of the California Medical Association; formerly emeritus professor of medicine, University of California Medical Department; aged 75; died, July 12.

Charles Lusby Pearson, Newton, Mass.; University of Maryland School of Medicine, Baltimore, 1883; an Affiliate Fellow of the American Medical Association; aged 73; died, September 8, of coronary thrombosis and gastric ulcer with hemorrhage.

Elias Harry Pofcher, Worcester, Mass.; Tufts College Medical School, Boston, 1904; member of the Massachusetts Medical Society; also a lawyer; alderman; aged 53; died, August 28, in the Beth Israel Hospital, Boston, of cirrhosis of the liver.

Bertram Edwin Marshall @ New Brighton, Pa.; New York Homeopathic Medical College and Hospital, 1899; served during the World War; on the staff of the Beaver Valley General Hospital; aged 60; died suddenly, August 30, of heart disease.

Joseph W. Largent, McKinney, Texas; University of Louisville (Ky.) School of Medicine, 1888; past president of the State Medical Association of Texas and the Collin County Medical Society; aged 71; died, July 31, of angina pectoris.

William Arthur Warner, Claude, Texas; Northwestern University Medical School, Chicago, 1894; member of the State Medical Association of Texas; served during the World War; aged 69; died, July 31, in a hospital at Amarillo.

Joseph Zimmerman Wild, Brooklyn; Victoria University Medical Department, Coburg, Ont., Canada, 1883; member of the Medical Society of the State of New York; aged 74; died, August 11, of carcinoma of the stomach.

Charles Wills King, Dayton, Ohio; Medical College of Ohio, Cincinnati, 1878; member of the Ohio State Medical Association; formerly superintendent of the Dayton State Hospital; aged 79; died, August 23, of senility.

Frank A. Winneman, Merrill, Wis.; Milwaukee Medical College, 1897; member of the State Medical Society of Wisconsin; on the staff of the Holy Cross Hospital; aged 70; died, August 25, of angina pectoris.

Samuel H. Snow, Kansas City, Mo.; Kansas City Hahnemann Medical College, 1908; member of the Associated Anesthetists of the United States and Canada; aged 62; died, August 23, of chronic myocarditis.

H. Marion Williams, Oklahoma City (registered in Oklahoma by the state board of health, under the Act of 1908); member of the Oklahoma State Medical Association; aged 62; died, in August, of heart disease.

Thomas T. Waggoner, Freeport, Ill.; Barnes Medical College, St. Louis, 1899; member of the Illinois State Medical Society; on the staff of St. Francis Hospital; aged 71; died, September 2, of heart disease.

Edwin A. Jarecki, Philadelphia; University of Michigan Medical School, Ann Arbor, 1891; for many years chief resident physician at the Jewish Hospital; aged 67; died, September 9, of heart disease.

Harold Payne Lawrence, Bay City, Mich.; Detroit College of Medicine, 1905; on the staff of the Mercy Hospital; aged 50; died, August 16, of injuries received in a fall from a second story window.

Gordon Flewellen Chambers, Columbus, Ga.; Atlanta College of Physicians and Surgeons, 1900; formerly member of the city council; aged 59; was found dead, August 2, of pulmonary hemorrhage.

John A. Welch, Letts, Ind.; Hospital College of Medicine, Louisville, Ky., 1898; member of the Indiana State Medical Association; aged 60; died, August 24, of uremia and hypostatic pneumonia.

Edward Kirtland Morton, Point Loma, Calif.; College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1884; aged 78; died, July 24, of myocarditis.

James Martin Melvin, St. Louis; Missouri Medical College, St. Louis, 1891; for many years member of the city health department; aged 68; died, July 24, of a self inflicted bullet wound.

Elmer Ellsworth Harrison, West Concord, Minn.; University of Minnesota Medical School, Minneapolis, 1897; member of the Minnesota State Medical Association; aged 68; died in June.

Jacob Warren Smith, Terre Haute, Ind.; Homeopathic Medical College of Missouri, St. Louis, 1891; aged 72; died, July 26, in St. Anthony's Hospital, of lobar pneumonia and myocarditis.

John W. Watzek, Davenport, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1881; aged 76; died, August 25, in Portland, Ore., of coronary thrombosis.

William G. Spence, Chestnut Bluff, Tenn.; Memphis Hospital Medical College, 1903; aged 53; died, August 28, in the Baptist Memorial Hospital, Memphis, of ruptured appendix and peritonitis.

Thomas Bernard Butler, St. Louis; St. Louis University School of Medicine, 1911; member of the Missouri State Medical Association; aged 49; died, September 1, of chronic nephritis.

Louis Legault, Cornwall, Ont., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, Que., 1901; aged 61; died, July 11.

Harry Irvin Shoenthal @ New Paris, Pa.; Jefferson Medical College of Philadelphia, 1906; past president and secretary of the Bedford County Medical Society; aged 52; died, July 10.

Fred H. A. Mallinson, Houston, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907); aged 56; died, August 23, of a self inflicted bullet wound.

John Joseph Loughlin, Wakefield, Mass.; Boston University School of Medicine, 1903; member of the Massachusetts Medical Society; aged 54; died, September 6, of cerebral hemorrhage.

Thomas Benton Mansfield, St. Louis; Barnes Medical College, St. Louis, 1904; formerly professor of anatomy at his alma mater; aged 63; died, July 21, of cerebral hemorrhage.

Francis Ernest Thornton, East Aurora, N. Y.; University of the City of New York Medical Department, 1886; aged 71; died, September 17, of uremia, myocarditis and nephritis.

Jonathan Blythe Core, Bethesda, Tenn.; Vanderbilt University School of Medicine, Nashville, 1892; member of the Tennessee State Medical Association; aged 63; died, July 12.

Chester A. Wright, Fulton, Ky.; Hospital College of Medicine, Louisville, 1907; aged 52; died, August 13, in the Western State Hospital, Hopkinsville, of cerebral hemorrhage.

Ernest Paul Wheeler, Long Beach, Calif.; State College of Physicians and Surgeons, Indianapolis, 1907; aged 56; died, July 27, in the Community Hospital, of acute coronary occlusion.

Emma E. Crook McKay, Hollister, Calif.; University of California Medical Department, San Francisco, 1892; member of the California Medical Association; aged 73; died, July 8.

Herman Corwin Homer, Cheyenne Wells, Colo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; aged 64; died, July 7.

William E. Kelsey, Monterey, Ind. (licensed in Indiana in 1899); also a druggist; for many years postmaster of Monterey; aged 75; died, August 16, of cerebral hemorrhage.

Reuben Ellsworth Mercer, Pittsburgh; Western Pennsylvania Medical College, 1892; aged 64; died, June 26, in the Southside Hospital, of lung abscess and hemorrhage.

Charles Wilbur Smith, Springfield, Mo.; Beaumont Hospital Medical College, St. Louis, 1901; member of the Missouri State Medical Association; aged 61; died, July 8.

Arthur Henry Reinstein @ San Francisco; Cooper Medical College, San Francisco, 1907; aged 50; died, August 17, in St. Francis Hospital, of cerebral hemorrhage.

De Witt Clinton Van Zile, New York; Baltimore Medical College, 1905; ship surgeon to the *Morro Castle*; aged 54; died, September 8, in the *Morro Castle* disaster.

Younger Pitts Robards, St. Louis; Barnes Medical College, St. Louis, 1902; aged 61; was found dead, July 6, of chronic myocarditis and pulmonary hemorrhage.

Harry Hood Whitten, Temple City, Calif.; Northwestern University Medical School, Chicago, 1896; aged 65; died, July 30, in Alhambra, of cerebral hemorrhage.

John Whalen Doyle, Boone, Iowa; University of Michigan Medical School, Ann Arbor, 1888; aged 77; died, July 31, of diabetes mellitus and carbuncle of the neck.

Clarence D. Whipple, Minneapolis; University of Minnesota Medical School, Minneapolis, 1903; aged 71; died, July 27, of arteriosclerosis and myocarditis.

George Clarence Shepard, El Cajon, Calif.; Harvard University Medical School, Boston, 1884; aged 80; died, July 20, of pulmonary tuberculosis.

William Samuel Taylor, Mount Airy, N. C.; Jefferson Medical College of Philadelphia, 1873; aged 84; died, August 29, in Greensboro, of heart disease.

Charles G. Rankin, Glastonbury, Conn.; Chicago Medical College, 1886; for many years health officer; aged 74; died, August 11, of chronic myocarditis.

Simon Horowitz, East Orange, N. J.; Syracuse University College of Medicine, 1892; aged 30; was found dead, September 6, of accidental asphyxiation.

Clark Watson Banks, Derry, Pa.; Toledo Medical College, 1888; aged 74; died, August 31, at the Latrobe (Pa.) Hospital, of chronic myocarditis.

John William Lorenz, Evansville, Ind.; Louisville (Ky.) School of Medicine, 1903; aged 76; died, July 28, of uremia and parenchymatous nephritis.

Samuel Dixon Mayhew, Wildwood, N. J.; Jefferson Medical College of Philadelphia, 1900; aged 60; died, August 24, in Millville, of heart disease.

George Parkin Stubbs, Pasadena, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1890; aged 68; died, August 15, of influenza.

John Tyler Williams, Washington, D. C.; Milwaukee Medical College, 1910; aged 56; died, July 21, of cerebral hemorrhage and hemiplegia.

Russel Bennett Miller, Chicago; Columbus Medical College, 1880; aged 77; died, September 19, at Gleason, Wis., of pulmonary tuberculosis.

James F. Smith, Martha, Ky.; Kentucky School of Medicine, Louisville, 1903; aged 57; died, August 27, of a self inflicted bullet wound.

Mary Muriel Currie MacLennan, London, Ont., McGill University Faculty of Medicine, Montreal, Que., 1927; aged 42; died, August 22.

Joel S. Morris, Fort Worth, Texas; Kentucky School of Medicine, Louisville, 1875; aged 85; died, August 18, of cerebral arteriosclerosis.

Max C. Handley, Longmont, Colo.; Kansas City University of Physicians and Surgeons, 1925; aged 38; was found dead, September 4.

Howard M. Wood, Mears, Mich.; Vanderbilt University School of Medicine, Nashville, Tenn., 1886; aged 85; died, July 23, of senility.

William Alexander McCracken, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1910; aged 47; died, June 22.

Nelson O. Brenizer, Austin, Texas; Homeopathic Hospital College, Cleveland, 1880; aged 80; died, August 7, of chronic nephritis.

Alfred W. Girvin, Calgary, Alta., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1905; aged 54; died, June 11.

J. T. Hawkins, Bartow, Fla.; University of Georgia Medical Department, Augusta, 1891; aged 69; died, August 9, of heart disease.

Fletcher T. Mixon, East Point, Ga.; University of Georgia Medical Department, Augusta, 1881; aged 79; died, August 8, of nephritis.

Jacob J. Simonds, Kingston, N. Y.; University of Buffalo School of Medicine, 1890; aged 76; died, August 3, of myocarditis.

Robert Edward Lee Hughes, St. Louis; Barnes Medical College, St. Louis, 1910; aged 62; died, August 31, of pneumonia.

Donald MacGregor Mackay, Vancouver, B. C., Canada; Jefferson Medical College of Philadelphia, 1896; aged 63; died, August 29.

Thomas Lowell Butters, Vancouver, B. C., Canada; University of Toronto Faculty of Medicine, 1913; aged 44; died, August 11.

Thomas Symes Genge, Verona, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1901; aged 64; died, June 29.

Joao Pinto, Los Angeles; Faculdade de Medicina de Lisbon, Portugal, 1903; aged 60; died, July 14, of arthritis and angina pectoris.

William Edward Sullivan, Brooklyn; Long Island College Hospital, Brooklyn, 1889; aged 67; died, September 4, of heart disease.

George S. La Moree, Highland, N. Y.; Albany (N. Y.) Medical College, 1872; formerly postmaster; aged 85; died, July 7.

Douglas Craddock Murden, Los Angeles; Meharry Medical College, Nashville, Tenn., 1913; aged 50; died, July 10.

Clarence Otho Jefferies, Savannah, Mo.; University Medical College of Kansas City, 1888; aged 81; died, July 11.

Harley N. Baker, Wayland, Mich.; Hering Medical College, Chicago, 1894; aged 70; died, August 24, of pneumonia.

Charles A. King, Sussex, N. B., Canada; College of Physicians and Surgeons, Baltimore, 1904; aged 59; died, June 11.

Elmer Otis Richardson, Marion, Ohio; Columbus Medical College, 1884; aged 73; died, July 6, of cerebral hemorrhage.

Hiram Orville King, Curwensville, Pa.; Jefferson Medical College of Philadelphia, 1893; aged 66; died, July 5.

Thomas P. Bradley, Sarnia, Ont., Canada; Trinity Medical College, Toronto, 1897; aged 61; died, June 30.

George B. Foster, Toronto, Ont., Canada; Pulte Medical College, Cincinnati, 1876; aged 85; died recently.

Isaac L. Edwards, Benton, Pa.; Jefferson Medical College of Philadelphia, 1870; aged 89; died, June 12.

Rufus S. Harvey, National City, Calif. (licensed in Nebraska in 1891); died, June 27.

BIRTH CONTROL AND CONTRACEPTION

To the Editor:—The editorial on "Birth Control and Contraception" in *THE JOURNAL*, September 8, is naturally of interest to the National Committee on Maternal Health, which since 1923 has been studying these and allied questions as problems of public health and the practice of medicine. Since 1929 we have conducted a systematic and comprehensive investigation into the nature and merits of various contraceptive products and methods. The result of the first three years study, done in cooperation with the University of Edinburgh, was published in a volume by Cecil I. B. Voge, Ph.D., F.R.S.E., F.R.S.M., under the title of "The Chemistry and Physics of Contraceptives" (London, Jonathan Cape, 1933).

Voge's study established the factual basis for the evaluation of contraceptives in terms of physics, chemistry and biology. The next step was obviously to apply the tests to the commercial products now most widely used and exploited, and concomitantly the development of a plan for the control of the contraceptive industry in the interest of a sound practice of preventive medicine.

The present undertaking has two phases: First, a laboratory and clinical investigation centered in London, under Dr. Voge's direction, for determining the harmlessness and efficacy of particular products, is concerned primarily with the development of appropriate tests and mechanisms for use in routine checking and evaluating of large quantities of material, as required by the dimensions of the industry and practice. Especial attention is given to American products. The second is an intensive and extensive study of medical-economic features, including methods of manufacture, testing, distribution, merchandising, and advertising through medical and lay channels. This is under the direction of our standards consultant, Mr. Randolph Cautley, business analyst.

Our ultimate objective is the development of a reference and standardization service, and consequent control of the practice of contraception by the medical profession, through its duly constituted authorities. We have accordingly been studying the existing laws and agencies that might be involved in a plan for control, such as the postal laws, the food and drug acts, the federal trade commission or national scientific and professional societies and boards of pharmacy and medicine.

Since 1924 the committee has repeatedly urged on the Board of Trustees of the American Medical Association, and especially the Council on Pharmacy and Chemistry, that it take these matters into serious consideration and furnish guidance in the choice of materials and methods. Until now the trustees have declined any such undertaking, as has the U. S. Public Health Service, when similarly approached.

Clearly, however, no private organization could serve adequately, and only the American Medical Association or a national governmental agency would function with the requisite scope and authority. The committee therefore welcomes the expression of interest by the American Medical Association, especially the final statement that "the situation now prevailing is warrant for some type of action leading to scientific control" and offers to place at its disposal our accumulated material and information, together with programs, plans and outlines of projects evolved during our studies of more than ten years.

Incidentally, the committee has long been interested in the question of the "safe period" as a birth control method and in 1927 published the first elaborate study and evaluation of available data (Dickinson, R. L.: *Am. J. Obst. & Gynec.* 14:718 [Dec.] 1927). In 1931 the matter was again reviewed

in the illustrated manual "Control of Conception" (Dickinson and Bryant, Baltimore, Williams and Wilkins Company, 1931) and we have been in touch with the later developments, various investigators and the rapidly accumulating literature.

Certain concrete achievements in the direction of scientific control are to be noted. Especially significant is the action of the *British Medical Journal* in adopting a policy of accepting advertisements of contraceptives, if and when their presumptive harmlessness and relative efficacy have been assured, and the truthfulness of the advertising accredited. Since early in 1933, Dr. Voge has acted as referee on the matter for the *British Medical Journal* and later for the *Lancet* and *Proctitioner*. In the spring of 1934 the *American Journal of Obstetrics and Gynecology* adopted a similar policy, with our committee as referee.

These mark the beginning of a program for the control by the medical profession of contraception as a recognized part of preventive medicine, for the primary object of such selective advertisement is not the negative one of censorship but the positive one of informing the doctor of reliable measures.

The whole situation with respect to contraception is changing so rapidly, and at so many levels and in so many directions, that any attempt to affect it must be both comprehensively conceived and decisively executed.

HAVEN EMERSON, M.D., Chairman.

WILBUR WARD, M.D., Chairman Executive Committee.

FREDERICK C. HOLDEN, M.D., Acting Secretary.

NATIONAL COMMITTEE ON MATERNAL HEALTH, INC.,

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

NERVOUS SYSTEM IN PERNICIOUS ANEMIA

To the Editor:—Is there anything that can be done to prevent complications due to pernicious anemia, especially posterolateral sclerosis? I have two patients under my care at the present time, both receiving treatment for pernicious anemia, one 55 and the other 60, who have developed symptoms of posterolateral sclerosis. They have done so in spite of the fact that they have been receiving liver treatment, which raised the blood count to practically normal level. Can the degenerative factors develop in the posterolateral cord at the same time that the anemia develops and only later show symptoms?

NATHAN STEINBERG, M.D., Philadelphia.

ANSWER.—The most serious complication of pernicious anemia is usually the disturbance of the nervous system. The development of posterolateral sclerosis may occur early or late in relation to the development of anemia and may sometimes occur under treatment sufficient to maintain a normal blood count. It is probable, however, that the neurologic complications will not usually develop in patients who are receiving large amounts of active material (liver extract or desiccated stomach) by mouth with regularity. If, under these conditions, paresthesias appear, the treatment immediately indicated is an increase of the dosage of active principle, irrespective of the blood level. It is usually easy to effect this increase by changing from oral therapy to therapy with parenteral liver extract; but if parenteral liver extract is already being administered, its dosage should be increased and so maintained for a period of months. It is of course important to use products known to be effective.

The first principle of the treatment of posterolateral sclerosis is prophylaxis; in other words, an increase of the potency of active material whenever symptoms referable to the nervous system appear, irrespective of the blood level or of the condition of the patient in other respects. In a general way, the longer the symptoms and signs of posterolateral sclerosis have existed, the greater the difficulty in treating them. If the complication has been present for six months or a year, further progress can be arrested with adequate amounts of effective substances, but the damage to the nervous system is probably not susceptible of repair. Although improvement of the objective neurologic

signs under these conditions will usually not occur, the relief of paresthesias is usually complete and there may be great improvement in coordination. No effort should be spared in persisting in large doses of active principle, especially in the use of liver extract parenterally administered and in orthopedic measures for the improvement of walking ability.

TREATMENT OF DUODENAL ULCER AFTER HEMORRHAGE

To the Editor:—Would you be good enough to suggest treatment of duodenal ulcer following hemorrhage, giving specific details as to amount of activity allowed and modification, if any, of Sippy diet and within what time limits?

M.D., Quebec.

ANSWER.—If there has been no emesis, the patient should be fed from the outset, beginning with small amounts of frozen or ice cold milk or cream followed by a powder of calcium carbonate, 1 Gm. (15 grains), and bismuth subcarbonate 0.3 Gm. (5 grains). These should be given fifteen minutes after and on the hour between feedings with water. Feedings should be every two hours from 8 a. m. to 8 p. m. In addition, atropine sulphate should be given, 0.4 mg. ($\frac{1}{150}$ grain), with water by mouth twice a day. The milk and cream feedings are gradually increased day by day until at the end of the week the patient is taking 8 ounces of milk and cream every two hours. Orange juice at this time may be added in increasing amounts. From this point on foods that go to make an ulcer diet are gradually added. At the end of the third or fourth day, if there has been no bowel movement, the patient should have a small retention enema of from 3 to 4 ounces of warm liquid petrolatum, and this is to be repeated once or twice a day until the patient has a bowel movement and kept up as long as necessary. All stools should be examined daily for occult blood. The hemoglobin and erythrocyte count should be made daily as an index to the cessation of bleeding. The patient's blood should be typed at the outset for possible transfusion, which may be necessary during the course of treatment. Frequent determination should be made of the blood chemistry, particularly the carbon dioxide, nonprotein nitrogen and sugar. If there is any tendency toward alkalosis, calcium carbonate should be omitted and tertiary calcium phosphate substituted. After the stools have become negative for occult blood, magnesium carbonate, 0.3 or 0.65 Gm. (5 or 10 grains) may be added to the powders. As a rule the average uncomplicated duodenal ulcer stops bleeding in a week or ten days. If bleeding persists beyond a period of two weeks' management and into the third week, one should seriously consider giving a blood transfusion and, if bleeding continues, surgical intervention for a complicated and indolent chronic ulcer should be seriously considered. If occult blood has disappeared from the stool, the patient should remain in the hospital for a period of three or four weeks and then from four to six weeks should be allowed to elapse before any roentgen investigation is done. Following the patient's dismissal from the hospital, one should determine possible foci of infection as etiologic factors in the life cycle of the ulcer. Particularly is this true of diseased teeth and tonsils, which, from the standpoint of empiricism, should be removed. If hemorrhage has been recurring for a period of years after the cessation of this hemorrhage, surgical intervention may be the wisest permanent procedure.

FLUID INTAKE IN EDEMA

To the Editor:—Will you clarify for me the problem of fluid intake in various types of edema? I was taught that it is not "work" for the kidney to put out water. I am not thinking so much of cardiac decompensation when obviously the entire circulation is impaired and the heart is the primary organ to be considered, as I am of nephritides and especially of preeclamptic toxemia. Please omit name and town.

M.D., Massachusetts.

ANSWER.—Toxemia of pregnancy is not characterized by one typical form of pathologic lesion but may manifest itself in one of three ways: (1) by general vascular injury, (2) by involvement of the renal glomeruli, and (3) by degenerative processes, especially in the liver and in the renal tubules. The renal disturbances in preeclamptic toxemia may appear as acute glomerulonephritis or as acute nephrosis. Edema is more characteristic of the second type than of the first.

Edema may be the result of (1) a decrease in colloid osmotic pressure of the plasma proteins, as in nephrosis, (2) an increase in permeability of capillaries, as in glomerulonephritis, and (3) an increase in hydrostatic pressure in the capillaries, as occurs with cardiac decompensation. These three types of edema may coexist in some cases. Estimations of the protein content of

edematous fluid may aid in the differential diagnosis. In nephritic edema the protein content of the fluid is low (less than 0.1 per cent). In the edema of glomerulonephritis the protein content is sometimes high (more than 1 per cent). In cardiac edema the protein content of edematous fluid is variable, but it generally is about 0.5 per cent. Water is filtered through glomeruli in enormous quantities, and about 97 per cent of it is reabsorbed through the tubules, since it is vital to the body and must not be lost. Edema may therefore result from diminution of glomerular excretion or increased tubular reabsorption, or from retention of fluid in diffuse intracellular tissue from disturbances in the concentration of the plasma proteins or electrolytes.

Although edema, of a certain amount at least, may be harmless per se, it seems good practice, regardless of the type of edema, to correct it, certainly to control it. This is done chiefly by strict attention to the patient's intake of salt and water and, if significant retention of urea is not present, by the newer mercurial diuretics and such diuretic salts as ammonium chloride, ammonium nitrate and potassium nitrate. The protein intake is a matter of distinct importance, as further depletion of body proteins may increase edema. In the edema of nephrosis (idiopathic or preeclamptic), when retention of urea generally is absent, the intake of water should be sharply lowered, perhaps to from 600 to 800 cc. daily; no salt should be added to the food during its preparation or taken when it is eaten. The protein intake may be generous, from 70 to 90 Gm. daily.

The presence of both edema and retention of urea presents a dilemma. A generous intake of fluid is desirable to lower the concentration of blood urea, but this may add to the edema. The lesser evil is to give a moderate amount of water, perhaps from 1,000 to 1,200 cc. daily, in order to foster the excretion of urea, and cautiously to ignore the edema for the time being.

DIAGNOSIS OF GENITAL INFECTION

To the Editor:—Three days after exposure, a man, aged 30, developed a copious, yellowish urethral discharge. After one urethral irrigation with plain distilled water and injections twice daily for four days of a weak silver solution, the discharge stopped except for a small drop in the morning. Numerous smears of the urethral discharges, including those from the massaged prostate, have so far failed to show microorganisms, in spite of the fact that they are teeming with pus and epithelial cells. The right lobe of the prostate was much larger than the left and somewhat spongy, but under massage the size seems to have decreased and the gland seems firmer. After the injections had been discontinued for twenty-four hours the discharge became as copious as it was the first day, but when the injections were resumed it stopped except for the morning drop. Neither before nor after the appearance of the discharge has there been the slightest pain in or near the genitalia, or the least discomfort on urination. The man is in perfect health but has had two chills in the evening, the second about a week after the first. Each chill lasted about half an hour. The urine is normal. The first few ounces of urine voided are invariably cloudy. As urination progresses the urine becomes clearer, but the rest is much clearer and gradually all of it is slightly turbid. He has never had any genitourinary trouble before. Can you suggest a diagnosis? Please omit name.

M.D., Illinois.

ANSWER.—The presence of a copious yellowish urethral discharge three days after exposure suggests strongly that there was an infection by the gonococcus. It is difficult to account for the origin of a profuse discharge, teeming with pus and epithelial cells without microorganisms, unless it is due to self medication by the patient; for example, urethral injections of strong solutions of mild silver protein, strong silver protein or silver nitrate. Under these circumstances the patient may be said to have a chemical urethritis, and this should disappear with cessation of the injections.

The fact that the discharge promptly recurs when local treatment is stopped suggests that the patient has an infection in the urethral glands. If this fact can be reasonably assumed, an examination of the anterior urethra with the urethroscope is in order and if infected glands or follicles are found they should be destroyed through the endoscope with a high frequency current.

The statement that the right lobe of the prostate was large and spongy would suggest that an old infection in the prostate is the cause of the trouble. In this event, treatment should be directed to the prostate gland; namely, hot sitz baths, mild prostatic massage, and local treatment of the urethra with mild irrigations of potassium permanganate or injections of mild or strong silver protein.

The presence of chills would corroborate the evidence of infection in the prostate, since infection of the anterior urethra is rarely, if ever, accompanied by chills and fever.

BLOOD SEDIMENTATION TESTS

To the Editor:—Will you kindly send me the technic, including the interpretation, of the Westergren method of blood sedimentation test?

HARRY L. PARKER, M.D., Lockport, N. Y.

ANSWER.—Westergren (*Ann. Rev. Tuberc.* 14:94 [July] 1926) has described a satisfactory method for determining the red blood cell sedimentation rate. Oxalated venous blood is used and the determination may be done at any time within three hours after venipuncture. The same blood can be used for blood chemistry. Only two readings, at fifteen and forty-five minutes, are required. The apparatus is cheap and the pipets are easily cleaned. Well mixed oxalated venous blood is drawn up to the zero mark on the pipet, the excess blood on the tip is wiped off, and the pipet is inserted in the special rack. The upper level of the red cells is read at fifteen and forty-five minutes after the start. Westergren recommended readings at one, two and twenty-four hours. The apparatus and pipets may be obtained from the Arthur H. Thomas Company, Philadelphia.

Also the Linzenmeier method is widely used. The tubes are 7 cm. long and 5 mm. in internal diameter. They must be watched until the cells reach the 18 mm. mark. Citrated blood is used. The Cutter method, given in Kolmer and Boerner's *Approved Laboratory Technic*, consists in drawing 0.5 cc. of 3-per cent sodium citrate and then venous blood to the 5 cc. mark of a syringe. The blood is mixed and placed in a special tube and read every five minutes for one hour and a curve drawn.

This test is not a special specific test for any disease. The rate of sedimentation is accelerated in active tuberculosis, acute inflammation, infectious diseases, carcinoma, pregnancy and the toxemias. It is of chief value in distinguishing between inflammatory and noninflammatory processes and for estimating the activity or progress of pulmonary tuberculosis. A normal curve is seldom seen in active tuberculosis of the lungs. In acute inflammations the rate of sedimentation is increased. An actively growing cancer is likely to give a greater rate than a slowly growing scirrhus carcinoma.

The rate is influenced by changes in plasma viscosity or in the number, size or hemoglobin content of the red blood cells. Significant increases in the rate are due to clumping of the corpuscles into larger aggregates than usual. This tendency to clumping is probably correlated with changes in the amount of plasma protein. Increase in globulin and also in fibrinogen causes an increased clumping and thus more rapid sedimentation. Increase in albumin seems to have an opposite effect.

Anything over 15 mm. in the forty-five minute period is definitely pathologic. A sedimentation rate of from 15 to 30 mm. in forty-five minutes represents a slight increase, from 30 to 50 mm. a moderate increase, and from 50 to 100 mm. a severe increase.

CARDIAC PAIN AND ANGINA PECTORIS

To the Editor:—A woman, aged 56, weighing 156 pounds (71 Kg.), of obese type, who appears to be 65, suffers excruciating pain over the upper part of the left arm, radiating from the scapula. According to the history given by her son, she has this attack every night. It comes on at about 11 o'clock and lasts ten minutes. She breaks out in perspiration but she does not complain of pain of the heart. She has at times pain around the left hypochondrium. Nothing but morphine gives her any relief, but when it is administered she usually gets over the attack. During the attack the son, who is an adult, has to step over her shoulder and twist her hands and hit the arm to relieve the spasm. The people are ignorant and uneducated miners. On physical examination I found the heart enlarged; the second aortic sound was accentuated; the Austin Flint murmur was absent; no murmurs were present. The Kahn blood test is negative; the urine is negative for sugar and albumin (acid in reaction); the patient asserts that the urine leaves stains on her underwear; the blood pressure is 220 systolic, 100 diastolic. After the administration of glyceryl trinitrate it came down to 178 systolic; the diastolic remained 100, within seven days. She tried various treatments. I placed her on potassium iodide, 10 grain doses (0.65 Gm.) three times a day, phenobarbital, 1½ grains (1 Gm.), at bedtime and glyceryl trinitrate, ¼ grain (0.6 mg.) every four hours. Is her angiospasm due to the arteriosclerotic condition? Would you consider angina pectoris without pain in the heart? (The pain is commencing around the left side of the neck and radiates downward through the arm, reaching the back also.) I may state that she gets amyl nitrate inhalant and ether during the attack as an inhalation. Hot towels or any physical therapeutic means have no effect. What shall I try? I cannot give her anything intravenously as she is fat and I cannot get to her veins. I thought of magnesium sulphate and dextrose but how shall I introduce it? Please omit name.

M.D., West Virginia.

ANSWER.—The character of the pain as described is quite typical of angina pectoris. The fact that it is not precordial in origin by no means excludes that diagnosis. There are many recorded instances of cardiac pain referred to either or both shoulders, arms and hands, the neck, the abdomen and

even more distant locations. The patient's age and evident long standing hypertension also favor this view. However, the fact that the attack always happens at night, presumably without effort, while not excluding angina, does not favor it. Failure of glyceryl trinitrate and amyl nitrite to relieve do oppose the assumption.

There is no reason to believe that peripheral arterial spasm would cause pain of such intensity without objective evidence of impairment of blood supply in the extremity involved. Localized muscle spasm is suggested by the description of the relief measures employed by the patient's son. If this is true, the condition should be evident.

Other possible causes to be considered are nerve pressure, the result of arthritis or other pathologic changes in the spine with nerve root irritation or involvement of the brachial plexus. Local bone and joint changes should be excluded. Diaphragmatic hernia of the von Bergman type may cause thoracic pain having the distribution of that of angina pectoris.

From the information given, the preponderance of evidence would favor the diagnosis of angina pectoris. Theobromine or theophylline compounds are often effective in the relief of pain of this type and may be used over long periods if there is no gastric distress. Theobromine sodium acetate may be given in 0.65 Gm. doses three times a day.

SODIUM IODIDE AND DRAINAGE OF SINUSES

To the Editor:—What value, if any, has sodium iodide, when injected intravenously for the purpose of inducing profuse drainage from infected paranasal sinuses? A case of anterior ethmoidal and frontal sinusitis with no drainage did not seem to progress well under treatment with ephedrine locally, nasal suction, dicalcium phosphate by mouth, haliver oil and viosterol by mouth and Proteolac (Searle) intramuscularly. The patient consulted another physician, who gave her two intravenous injections of a solution containing something like the following to 20 cc. of solution: 32 grains (2 Gm.) each of potassium iodide, sodium iodide and hypiodides (?), three-fourths grain (0.05 Gm.) of guanacolate (?), and one-fourth grain (0.016 Gm.) of potassium fluoride. Following two injections forty-eight hours apart, there was moderate drainage of clear fluid from the nose, and relief from pain. The right frontal sinus, formerly dark to transillumination, had cleared up about 50 per cent. Do you know of any preparation like this on the market and what is its value? Please omit name.

M.D., Ohio.

ANSWER.—The injection of a hypertonic solution, such as suggested, in addition to producing the effect of iodides usually produce, seriously alters, for a time at least, the electrolyte balance and the colloid equilibrium. It is not easy to believe that two injections intravenously forty-eight hours apart of a solution such as described would have a curative effect on sinusitis. In fact, there are cases on record in which the opposite has been noted and the therapeutic use of iodides, on the contrary, has been stated to produce sinusitis. Hence one must consider spontaneous recovery, without relationship to the therapy employed.

As said, intravenous medication of this type has definite risks because of the disturbances it produces. In addition, one must consider the delayed toxic effects of iodides in those susceptible. Iodides given by mouth or in any other way increase the secretions from the respiratory tract and do it efficiently if given orally. There is no reason to believe that iodides given in any fashion have a particularly curative behavior in sinusitis. The promiscuous use of medication intravenously should be discouraged unless for specific effect. The risk taken, then, is overbalanced by the benefit to be derived.

INTRAPERITONEAL TRANSFUSION OF BLOOD

To the Editor:—Is it necessary to type blood for intraperitoneal blood transfusion for an infant? What are the dangers of intraperitoneal blood transfusion and how are they avoided? Please omit name.

M.D., Connecticut.

ANSWER.—Blood injected into the peritoneal cavity is absorbed into the blood stream without much change and constitutes a true transfusion. Therefore the blood must be matched to insure compatibility. Some authors state that blood grouping tests are unnecessary with this procedure, but this is a dangerous assumption. Cases have been observed with moderate reaction following intraperitoneal transfusion from donors of the same group when cross agglutination had not been carried out. There also seems to be a popular idea among the profession that it is not necessary to carry out compatibility tests when the patient to be transfused is a small infant. While it is true that only a small number of infants below 6 months of age have fixed blood groups and that in many cases no reaction would occur in the absence of compatibility tests, the fact is established that some infants have fixed blood groups early in infancy. Thus the same careful procedure that is used in

choosing donors for intravenous transfusion in adults must be observed in preparing to transfuse infants by the intraperitoneal route.

With these facts in mind, the dangers of intraperitoneal blood transfusion are first in the technic and secondly in the choice of the patient to be transfused. Under errors in technic may be mentioned the possibility of penetrating the bowel or bladder. This can be easily avoided by making sure that these organs are completely evacuated before transfusion. A fold of the abdominal wall should be picked up and a short bevel needle inserted in the median line 2 inches below the umbilicus. The citrate solution should be freshly prepared and should not be buffered with dextrose. Old citrate solution and dextrose act as a peritoneal irritant. With regard to the patient, the contraindications are the same as for any other type of transfusion with the addition that it should never be used when there is any question of intra-abdominal disease. Whenever abdominal discomfort may be disadvantageous, as in severe cardiac disease or acute pulmonary infections, its use should be carefully considered. Finally, certain gravely ill infants have impaired capacity to absorb blood from the peritoneal cavity. Cases are on record in which a large part of the injected blood has remained in the peritoneal cavity as long as a week. Whenever there is any uncertainty as to absorption, blood should be given, if possible, by the intravenous route.

TREATMENT OF SEBORRHEIC DERMATITIS

To the Editor:—What is the most modern treatment of dermatitis seborrhoica (eczema seborrhoicum) of the scalp? Is an eruption, acute in onset, accompanied by moderate tenderness and mild itching, before the appearance of vesicles, which are pinhead in size and slightly elevated, with ease of rupture, exuding a thin serous fluid, the underlying layers of exposed skin appearing red and glossy also an eczematous condition? What is the most modern treatment of this condition? These conditions have appeared in the same person. What is the duration of the disease and what is the prognosis? The interdigital spaces of the fingers of the hand are the seat of this eruption, the condition appearing to extend to the dorsum and palmar surface also. Kindly omit name.

M.D., New York.

ANSWER:—The treatment of seborrheic dermatitis has not changed recently, but it has been discovered that some cases resembling this disease are caused by fungi. Salicylic acid, sulphur, resorcinol and the various tars are still the basis of the treatment. Ultraviolet radiation and roentgen rays are valuable aids. For ordinary cases, 3 per cent of salicylic acid and 5 per cent of sulphur in ointment of rose water is satisfactory. If action is slow, various strengths of the other drugs may be added, or the actinic rays may be used. Whitfield ointment, salicylic acid in varying strengths with twice as much benzoic acid in ointment of rose water, is successful in some cases, probably in those caused by fungi. The dermatitis between the fingers in the case under discussion suggests a monilia infection called *erosio interdigitalis blastomycetica*, and it is only reasonable to suspect that the scalp disease may be due to the same infection. The organism can be cultivated easily on Sabouraud's medium or other sugar mediums at room temperature. If this surmise is correct, daily swabbing between the fingers with half strength tincture of iodine or a 5 per cent solution of iodine in benzene should give prompt results. After apparent healing the treatment should be continued for some time to prevent recurrence, alternating with weak Whitfield ointment to avoid too much staining. The disease tends to recur, presumably by persistence of the infection in the scalp, under the finger nails or in the skin of the hands.

SPINAL ANESTHESIA IN CHILDREN

To the Editor:—What is the current opinion about the safety of spinal anesthesia in children? What dosage of procaine hydrochloride would you recommend for a child 2½ years of age? A child, aged 2½ years, is operated on under spinal anesthesia, and a gangrenous appendix with a localized peritonitis is found. Within twelve hours a temperature of 109.5 F. develops and nystagmus, convulsions and coma are noted in rapid succession, with a fatal outcome. No other physical signs suggestive of any other medical condition can be elicited. Would you consider this death the result of spinal anesthesia? Necropsy was not permitted. Kindly omit name.

M.D., New York.

ANSWER:—Spinal anesthesia has been advocated by Rocher (*Arch. de méd. d. enf.* 25:705 [Dec.] 1922), who used a dose of from 20 to 80 mg. of procaine for operations on children whose ages ranged from 4 to 15 years, by Junkin (*Canadian M. A. J.* 28:51 [Jan.] 1933), who used spinal anesthesia mainly for orthopedic operations on the lower extremities of children, and by Balacesco (*Bull. et mém. Soc. nat. de chir.* 57:370 [March 14] 1931), who used spinal anesthesia in 826 cases in which the patients were children, 150 of whom were between

the ages of 3½ years and 7 years. For those who were from 3½ to 5 years old, he used a dose of from 30 to 40 mg. of procaine. Salazar de Souza (*Arch. de méd. d. enf.* 35:441 [Aug.] 1932) stated that in a series of operations on 540 children the usual dose of procaine he had used was from 40 to 50 mg.; the youngest child in his series was 32 days old, and twenty-five others were a year old or younger. Forgue and Basset (*La rachianesthésie; sa valeur et sa place actuelle dans la pratique*, Paris, Masson et Cie, 1930) do not advise the use of spinal anesthesia for children less than 15 or 16 years of age. Their questionnaires led them to believe that the majority of surgeons reject spinal anesthesia for operations on children.

The dose of procaine to be used for children should be 1 mg. for each pound of body weight, as in adults, debility decreasing the dose in relation to its severity. Death in the case described probably was not due to spinal anesthesia.

USE OF PARATHYROID IN ARTHRITIS

To the Editor:—1. I should like to know whether there are any clinical data to support the use of parathyroid extract-Collip in the treatment of chronic arthritis deformans. 2. Is there any new treatment for this arthritis?

K. A. ANDERSON, M.D., Charlotte, Mich.

ANSWER:—1. A consistent and uniformly demonstrable alteration in calcium metabolism in arthritis would seem to be a prerequisite for the rational use of parathyroid therapy.

In atrophic (infectious, proliferative, rheumatoid) arthritis there is atrophy of the bony epiphyses of the affected joints, at least in well advanced cases. In hypertrophic (senescent, degenerative, osteo-) arthritis there is marginal osteophyte formation and thickening of subchondral bone. These alterations in the calcium deposition of articular bone have led to a search for some general disturbance of calcium metabolism. Studies on the calcium content of blood and serum in cases of "chronic arthritis," of infective, hypertrophic and atrophic arthritis, of fibrositis and of sciatica have given variable results. A few have reported a decrease in blood calcium, both total and ionic (Price, 1923; Vine, 1924). A dozen or so investigators have found evidences of a moderately increased blood or serum calcium, a little more frequently in hypertrophic arthritis than in atrophic arthritis or in nonarticular rheumatism (Goldthwaite, Painter and Osgood, 1904; Lindemann, 1914; Mark, 1923; Weil and Guillaumin, 1923; Watchorn, 1925; Horowitz, 1926; Copp, 1930). Many others, among them Pemberton and Foster (1920), Nachlas (1927) and especially Buckley and Race, have concluded that the calcium content of blood and serum presents no marked deviations from the normal in the various types of arthritis. Nor did they find any significant disturbance in the relative proportions of diffusible and nondiffusible calcium. Studies in urinary calcium of arthritic patients are meager and do not permit conclusions to be drawn. No consistent alterations in phosphate metabolism or in the phosphatase content of the blood have been found (Buckley and Race).

Regardless of these observations, in progressive diseases of uncertain origin, such as the arthritides, one is tempted to note, empirically, the effect of the newer endocrine preparations. Grove and Vines administered parathyroid extract (*Brit. M. J.* 1:791 [May 20] 1922). Snell and Hensch studied the effect of parathyroid extract (Hanson)-N. N. R. given to a patient with chronic infectious arthritis (*Mimosa Med.* 13:8, 1930). Weissenbach, Francon, Perles and Seidemann also administered parathyroid extract (*Bull. et mém. Soc. méd. d. hôp. de Paris* 54:1843 [Dec.] 1930). None of these investigators apparently have pursued these lines of treatment to any extent.

During the past five years there has been an attempt on the part of several (Oppel, 1929; Leriche, Simon and Jung, 1931; Ballin and Morse, 1931; Funsten, 1933) to include "ankylosing polyarthritis" and spondylitis deformans in the syndrome of hyperparathyroidism. Parathyroidectomy (sometimes only unilateral) has been performed by them in a number of instances with reported benefits. It is admitted (Camp, 1932) that, owing to the marked decalcification in parathyroidism, the surfaces of the joints may collapse and thus resemble somewhat a destructive arthritis, but in true arthritis the chemical changes characteristic of parathyroidism are absent. Lièvre, the French authority, and Bauer, one of the chief American investigators of this disease, have both emphatically objected to such adulteration of the syndrome of hyperparathyroidism by the inclusion of arthritis. Bauer has stated that arthritis is not associated with or due to experimental or clinical hyperparathyroidism. To this Compere and Camp agree.

It is possible that the parathyroids and other parts of the endocrine-sympathetic system may be affected somewhat by the disease whose major manifestation is arthritis. One must conclude, however, that no proof so far exists that either atrophic

or hypertrophic arthritis is related to any primary deficiency or to any superabundance of parathyroid hormone, and that either the use of parathyroid extracts or resort to parathyroidectomy must be considered an experimental procedure entirely.

2. The "newest treatment" for chronic arthritis is fever therapy by means of diathermy, radiotherapy or, more recently, the safer and simpler hot, air conditioned cabinets. Fever sessions are given once or twice weekly. The patient's temperature is raised fairly rapidly to from 104 to 105 F. Certain special precautions are necessary to avoid untoward reactions, but when these are taken the procedure seems relatively safe.

The results to date are variable. Some assert that about 35 per cent of patients subjected to a series of from three to six fever sessions note marked amelioration in, and at times complete cessation of, the activity of the disease. This method of treatment is too new for final evaluation.

GLYCERIN AS SCLEROSIS INDUCING AGENT

To the Editor:—Can you give me any definite information as to the sclerotic action of glycerin, either pure or dilute, when injected into the tissues? Also, how strong a solution of glycerin can be used without discomfort to the patient? Glycerin and dextrose have been used for the injection of varicose veins. Just how much of the result is due to the dextrose and how much to the glycerin, I do not know. Also, can you advise me whether glycerin diluted say 50 per cent with water is more slowly absorbed when injected into the tissues than water? In other words, would an anesthetic dissolved in a solution of glycerin be absorbed more slowly and so give a more prolonged anesthesia than an aqueous solution? Lastly, can you advise me whether a solution of phenol in glycerin is less caustic if injected into the tissues than an aqueous solution of phenol? In other words, does glycerin act as an antidote to any degree to the local action of phenol?

W. A. HINCKLE, M.D., Peoria, Ill

ANSWER.—The sclerosis inducing action of glycerin is due to its hygroscopic power. Hence it is present only when the fluid is injected in relatively high concentration. There is some discomfort when glycerin in any concentration is injected subcutaneously. As both dextrose and glycerin act by withdrawing water from cells, the share of each of them in producing the phlebitis will depend on their relative concentration. Glycerin delays the absorption of fluid when injected into the tissues. It will also delay the absorption of chemicals, and the more so the more soluble the substance is in glycerin than in the tissue fluids. A solution of phenol in glycerin is less caustic than an aqueous solution. To a certain extent, glycerin is an antidote to the local action of picric acid; but it is less efficient as an antidote than alcohol in the treatment of phenol corrosion.

BLEEDING IN THE NEW-BORN

To the Editor.—A primipara was delivered at term, twenty hours after the beginning of labor. Ten hours before delivery she was given one sixth grain (0.01 Gm.) of morphine and $\frac{1}{320}$ grain (0.5 mg.) of scopolamine hydrobromide. The pains were rather weak and ineffective, and dilatation of the cervix was completed manually. The application of low forceps was preceded by an episiotomy. The fetus was in the left occipito anterior position. The delivery was accomplished easily, under a short chloroform anesthesia. The progress of the mother has been uneventful. The condition of the baby immediately after birth was entirely satisfactory. Sixteen hours after birth the baby vomited a moderate amount of bright red blood. The baby was given 10 cc of the father's blood intramuscularly. For four hours the baby's condition seemed satisfactory. Twenty hours after delivery the baby passed a large amount of clotted and fresh blood from the rectum and died immediately from the hemorrhage. The entire gastrointestinal tract was removed and examined. No malformation was present and no pathological changes other than a spongy condition of the mucosa of the stomach, ileum and colon were noted. No specific bleeding point could be found. The mother died severely ten years ago following a tooth extraction, and five years ago following a tonsil operation, otherwise there is nothing of importance in the mother's history. Two nuns (0.12 cc) of solution of pituitary was given three times at intervals of twenty minutes after the cervix was completely dilated. Please omit name. M.D., Colorado.

ANSWER.—The baby in this case most likely had melena neonatorum, or hemorrhage of the new-born, as evidenced by the vomiting of blood and the passage of old and fresh blood from the rectum. No mention is made of signs or symptoms of cerebral hemorrhage, which may occur as part of the syn-

drome of melena neonatorum or independently. Cerebral hemorrhage may, of course, take place after spontaneous labor as well as after instrumental deliveries and the use of solution of pituitary. Hence it is by no means always the fault of the attending physician. The cause of bleeding of the new-born is not definitely known. It is unfortunate that the bleeding time and coagulation time of this baby were not determined. The most effective remedy for bleeding of this type is transfusion of whole blood.

FIBROUS SCLEROSIS OF CORPORA CAVERNOSA OF PENIS

To the Editor.—I have under my care a case of fibrous sclerosis of the corpora cavernosa (multiple) of the penis. The patient is 47 years of age and has absolutely no disease condition, though he had a gonorrheal infection about twenty-five years ago. Physically he has no defect whatever. What would be your procedure in the handling of such a case, and also what is the usual outcome as to relief? If these questions are to be published, kindly withhold name.

M.D., Michigan.

ANSWER.—Fibrosis of the corpus cavernosum of the urethra or the penis may occur as a result of a thrombus associated with infection or as a sequel to severe gonorrhea, periurethral abscess, septic wounds or severe contusion of the penis.

The penis assumes a lopsided and distorted stance on erection. It bends toward the lesion, where fibrosis prevents vascular engorgement and frequently produces pain.

Early treatment consists in giving iodides and eitrates by mouth and the local application of fomentations and gentle massage to reestablish circulation. In old-standing cases the prognosis is bad. Bromides may be given at night and the fibrous cords divided surgically.

Massage over a sound may be of some value with dilation of the urethra, which is usually narrowed.

When the fibrous bands are localized, excision with suture of the normal ends of the corpora cavernosa may be tried. The patient should not expect too much, as the penis will be shortened and it may take considerable time before erection becomes established.

DEPRESSION AND NARCISSISM

To the Editor.—A man, aged 28, of good appearance and with a university education, came to me with the complaint of morbid depression. He cannot get out of his mind the idea of the futility of things. He has perfect insight into his condition, but it seems that he cannot alter it. He states that the only time he is happy is when he is unconscious of self, only when sleeping or absorbed in reading. Otherwise his mind is in a continuous depressed state and he feels shy in talking to people. He cannot become interested in the commonplace things of everyday life. He states that he has been introspective and melancholy and withdrawn in himself all his life. He has no hallucinations, no warped ideas, except in the evil of the world and the drabness of existence, which he exaggerates in his own mind. He has no physical complaints, except a disability to concentrate well unless he deliberately tries to shake off his gloom, which he finds it hard to do. He is of normal weight. No defects were found on examination except a high degree of astigmatism in the left eye, which has been corrected as well as possible by a competent eye man. The sclera has a slight yellow tinge. The Wassermann reaction is negative. The blood count and the urine are normal. I have had him take phenobarbital when he feels terribly depressed. Also I have made him take saline laxatives. His main contention is that, because of his gloom and self-consciousness and inability to become interested in people or things, he is a poor companion. His continuous apprehensive gloom keeps his mind in a blank as far as outside events go, and thus he is reluctant to inflict himself on others, as much as he would enjoy being "normal" and enjoying the companionship of others. He would like to become interested in others, but his self-consciousness or self interest will not let him. He is afraid that others think him peculiar. Materially he is fairly well off and he has fair prospects if he can only snap himself out of it. The reason I write to you about this case is that I am interested in it. I am afraid that the patient may be contemplating suicide. I wonder if a psychoanalyst would do him good. Also where is a psychoanalyst near here to whom I could send him? I do not think that change of scene would help him, as he could not get away from his thoughts. Is this a case of psychasthenia?

M. J. FRANK, M.D., Beacon, N. Y.

ANSWER.—It is just as difficult to make a diagnosis in psychiatry without examining the patient personally as it is in other fields of medicine. The picture described is that of a chronic depression which seems to be a reaction to a strong withdrawal of interest from the external world, which leads to an incapacity of having any positive attachments outside the patient's own person. Such a self-centered attitude (narcissistic state of mind) often leads to inner conflicts, as it provokes self criticism and even feelings of guilt. In this case the depression apparently is not a reaction to any external event but a chronic state of mind which has persisted for a long time, and therefore it must be assumed that it is based on deep emotional conflicts. Only if the latter are influenced can a radical change

be expected. The therapy of choice, if this diagnosis is correct, is psychoanalysis.

Other psychotherapeutic approaches, such as persuasion or suggestion, would only touch the surface and can be employed in cases in which the morbid state of mind develops mainly as a reaction to an acute traumatic experience.

There are quite a series of competent psychoanalysts in New York, a list of which can be obtained from the New York Psychoanalytic Society, 324 West Eighty-Sixth Street, New York City.

RECURRENT UTERINE BLEEDING

To the Editor—A white woman, aged 27, consulted me, March 24, 1934, because of uterine bleeding since the onset of her last period two months previously. The hemorrhage was moderate, with no clots. She had a similar attack of menorrhagia ten years ago, which cleared up readily with some liquid medication orally, and a period that lasted one week four years ago, which ended apparently with the help of fluidextract of ergot. The present attack failed to clear up under fractional doses of the same drug. Catamenia started at 13, the periods being irregular (every three to six weeks) and lasting four days. The flow is moderate and usually clots. The patient had scarlet fever, measles and chickenpox in childhood. She stated that she had never had intercourse and said that there never had been leukorrhea. Examination revealed no apparent abnormalities, except for hemorrhage from the uterine cavity. The blood pressure was 116 systolic, 72 diastolic. Hemoglobin was 74. The bleeding time was two and one-half minutes, the coagulation time five minutes. (At a later date the patient said that she bled profusely and for a long time from cuts of the fingers and hands. A brother had severe epistaxis in his youth.) The urine was normal. I made a diagnosis of functional menorrhagia and prescribed a remedy containing ergot for oral administration. In six days the bleeding had practically ceased. Sixteen days later the uterine hemorrhage recurred, was profuse in amount, and to date (two weeks after the onset) still persists to a slight degree in spite of medication and bed rest. I think that the patient is practically over this attack but I fear a recurrence. The patient is working and wishes to avoid recurrence of this disorder. Any suggestions that you can give will be appreciated. Please omit name. M D, Ohio.

ANSWER—Although recurrent uterine bleeding in an unmarried woman of 27, without demonstrable evidence of pelvic disease, is usually ascribable to functional disturbance of the ovaries or other endocrine glands, diagnostic curettage is advisable because one sometimes encounters a submucous fibroid that is responsible for the bleeding. In the event that the curet reveals endometrial polyps, it is to be remembered that overgrowth of the endometrium is a frequent accompaniment of functional bleeding.

The care of functional uterine hemorrhage is often difficult and unsatisfactory. Many patients have a low basal metabolic rate. In these cases thyroid extract is almost specific.

Hypodermic injection of the pituitary-like luteinizing hormone has recently been used with success, but its value remains to be determined.

Röntgen treatment of the ovaries may be depended on to control the bleeding, but there remains the likelihood of permanent injury to the ovaries of younger women. The same would appear true of fractional intra-uterine applications of radium, although Keene is convinced of its therapeutic value and believes that radium in small amounts is harmless. Many gynecologists hold that supravaginal hysterectomy is preferable and is less radical because it spares the ovaries.

In selected cases of uterine retrodisplacement with associated functional bleeding, operative replacement of the uterus and ovaries is followed by a gradual return to regular menstruation, the result of reestablishment of normal ovarian function.

DANGERS OF BENZENE DICHLORIDE

To the Editor—Is it injurious to breathe air containing small amounts of the insecticide paradichlorobenzene? I have an 18 months old baby. When the nursery door is open to allow ventilation, fumes of paradichlorobenzene, which has been liberally used to protect clothing from moths in adjacent closets, floats into the room and the odor is rather distinct. Will this injure the baby? Please omit name.

M D, New York.

ANSWER—Paradichlorobenzene (benzene dichloride, dichloride) as used as a disinfectant is not known to produce harm to persons. Being a chlorinated hydrocarbon, it at once is to be associated with a number of related substances of well known toxicity. The fact that this crystalline substance becomes liquid at 53 C. and boils at 172 C. may be related to its apparent harmlessness, since these vapors are not freely produced at ordinary temperatures. While no equal significance should be attached to any genuine prospect of harm to this infant, it is felt that all possible pungent or disagreeable odors should be eliminated from all households. Offensive odors promote shallow breathing, nausea and mental irritability.

THROMBO-ANGITIS OBLITERANS

To the Editor—A man, aged 33, married in 1918, has one child 14 years old. He had the usual childhood diseases. Six months after the patient married he got wet in a rain and hail storm. Two days after the wetting he got stiff and stayed in bed for three months. In 1920 a mule bit him on the right forefinger, causing it to get sore. After enduring this condition for three months he had the finger amputated, and it took a month to get well. In 1924 the right little toe got sore and stayed that way for four or five months, after which he had the little toe amputated. The right thumb in 1929 got sore and stayed that way for three months. He had the thumb removed but healing did not occur and he had to have pieces removed five different times before the wound healed. In 1930 the left big toe had to be amputated, and now the right big toe is infected. The right big toe has been sore for a month and a half. The toe nail is off. The patient states that it just came off. All the nail bed has some necrotic tissue on it. It exudes some pus all the time. Around the necrosis the tissue is red and inflamed. The inflamed red tissue runs up into the foot a way. But it does not seem to be swollen to any degree. A thin ointment of balsam of peru in castor oil gives him the most relief. This is applied after a light treatment of x-rays and is the only treatment I have given him, thinking it might be ringworm of the nail; but it is not that. Examination of the blood is negative; the urine is negative for sugar. The blood pressure is 122 systolic, 80 diastolic. The patient has one bad tooth. He has been a little nervous for the past six months. He weighs 156 pounds (71 Kg.) and is 5 feet 10 inches (178 cm.) high. It looks like Buerger's disease, thrombo-angitis obliterans. If it is, please give me the best treatment so I shall not have to cut off his toes and fingers.

HUGH DAVIS, M.D., Seguin, Texas.

ANSWER—The successive involvement of the digits of the upper and lower extremities suggests that the diagnosis of thrombo-angitis obliterans may be correct, but the information supplied in the history is insufficient to establish the diagnosis. If pulsation is absent in the vessels of the extremities and if there is a history of the excessive use of tobacco, the diagnosis of this disease would be more certain.

Treatment for thrombo-angitis obliterans consists in intravenous injections of 5 per cent sodium chloride solution three times a week. The initial dose is 150 cc. and all subsequent injections 300 cc. Treatment is given on alternate days by the gravity method into a vein at the elbow. The solution must be prepared with freshly distilled water and immediately sterilized to avoid contamination. Additional details in regard to the treatment have been published in *THE JOURNAL*, June 5, 1926, page 1759, March 17, 1928, page 831, and May 31, 1929, page 1730.

If pain is severe, blocking of the peripheral nerves to produce anesthesia of the involved toe affords instant and complete relief. Details of this procedure can be found in the *Annals of Surgery* 98:55 (July) 1933. Complete cessation of the use of tobacco is essential. Weight bearing on the affected foot should be avoided by the use of bed rest or crutches until the ulcer is healed. A boric acid wet dressing should be applied to the toe until the infection is controlled, and then bland ointments may be used.

DIAGNOSIS OF WHOOPING COUGH

To the Editor—Is there any absolute method of diagnosing whooping cough before the cough reaches the spasmodic stage? Is the leukocyte count of more than suggestive value?

II. H. MUHLBERG, M.D., Reading, Pa.

ANSWER—The most nearly absolute method of diagnosing whooping cough before the whoop is to let the patient cough on a petri dish, containing a suitable medium, held 15 or 20 cm. from the mouth. No growth on the plate would not exclude the disease, but the development of colonies of the bacillus of whooping cough on the plate would justify a positive diagnosis. This "cough plate" method should be used more than it is in the early diagnosis of whooping cough.

Leukocytosis with a relative increase in the small lymphocytes usually appears in the early part of the convulsive stage and is regarded as a valuable diagnostic sign.

DOSAGE OF EPHEDRINE

To the Editor—A man, aged 36, has been complaining of fatigability, relieved by short periods of rest, for a long time. No organic abnormalities to account for this complaint have been discovered. I have prescribed for him ephedrine sulphate, one eighth grain (0.008 Gm.), to be taken three times daily. Is any harm to be expected from the prolonged and continued use of the drug in the dosage prescribed? Kindly omit name.

M D, Pennsylvania

ANSWER—No ill effects are likely to result from such dosage excepting that, as it is merely symptomatic therapy, if the condition is the result of excessive work this stimulation might make the final collapse still more disastrous.

PREGNANCY WITH ALBUMINURIA

To the Editor:—Kindly give me your opinion as to the advisability of a pregnancy in a woman, aged 30, who has been known to have albumin in the urine for the past ten years. During this time a number of tests have been made, at which times the renal function tests and blood chemistry have been normal. At the present time these tests are well within normal limits, the blood pressure being 124 systolic, 90 diastolic. This is apparently not a case of orthostatic albuminuria.

VERNE E. EASTMAN, M.D., Wausau, Wis.

ANSWER.—This woman may safely be advised to become pregnant, though she will have to be watched closely because not infrequently latent nephritis becomes apparent only during a pregnancy. The patient's urine should be examined both macroscopically and microscopically every two weeks during the first six months and every week thereafter. The blood pressure should likewise be checked with the same frequency and the patient's weight should be recorded at each visit. As a prophylactic measure, the patient should eliminate from her diet almost all table salt and condiments. Proteins may be eaten with impunity. Should the amount of albumin in the urine increase markedly and especially if casts or other evidence of kidney damage appear in the urine and the blood pressure rises, the pregnancy may have to be terminated.

ERUPTION OF TEETH

To the Editor:—In a child of 6, with all the deciduous teeth still firmly intact, the lower central incisors are beginning to erupt behind the deciduous. Is it necessary to extract the deciduous in order that the permanent may erupt properly? Kindly omit name.

M.D., New York City.

ANSWER.—The deciduous teeth should always be extracted immediately when the permanent teeth are detected erupting behind them.

INJECTION METHOD IN HYDROCELE

To the Editor:—In THE JOURNAL, July 28, page 281, a subscriber writes to ask if the use of sodium morrhuate is practical in the treatment of hydroceles. It is unfortunate that the inquirer was not referred to the comprehensive article by Kilbourne and Murray on the "Injection Treatment of Hydrocele" published in *California and Western Medicine* (37:3 [July] 1932). After extensive experimental investigations they employed a solution of quinine and urethane with excellent results. Kilbourne and Murray do not employ sodium morrhuate, as the solution is nonbactericidal, although Floyd and Pittman (*Georgia M. A. J.* 23:63 [Feb.] 1934; abstr. THE JOURNAL, May 12, p. 1641) have employed sodium morrhuate with the addition of a bactericidal drug with excellent results. Kilbourne and Murray found the use of quinine and urea solution, as recommended in your reply to the inquirer, impractical on account of the pain produced following the injection. For the last eighteen months, I and at my suggestion two of my colleagues, Dr. Charles R. Marquardt and Dr. James C. Sargent of Milwaukee, have employed the technic of Kilbourne and Murray in over thirty hydroceles with excellent results. It is our impression that the future will see a revival of this form of treatment of hydrocele and, with the use of the newer sclerosing solutions, we feel that the results will be entirely satisfactory. I was greatly pleased to see the fine answer given to the inquiry, as previously mentioned, in THE JOURNAL.

GEORGE H. EWELL, M.D., Madison, Wis.

CLIMATE AND SINUSITIS

To the Editor:—In an answer to a correspondent concerning residence for a case of sinusitis, I find San Diego recommended. I must disagree with this advice. Myself a sufferer for many years, I went there and found it unsatisfactory and was strongly advised by a prominent medical man not to remain. However, I do agree that Arizona is the best climate we have in this country. Tucson and the vicinity is all right. One must not get the idea that it is summer in winter in any part of this state. One thing that must be impressed on all these sufferers is that one winter or one summer will not suffice but, like tuberculosis, the disease requires a long if not permanent residence to assure or even promise a cure. I spent three winters of five months each north of Phoenix and had no severe attack, but on the way home on the last visit developed one on the train. Florida also is not a good place. I had two severe attacks there; i. e., on the Gulf Coast.

HENRY WALLACE, M.D., New York.

KALA AZAR IN TEXAS

To the Editor:—In Queries and Minor Notes in THE JOURNAL, September 8, a Texas physician inquires as to the possibility or probability of kala azar occurring in Texas. The answer made to the query is correct, but probably the correspondent should be referred to the paper by Katharine Dodd and Edna H. Tompkins on Histoplasmosis, which appeared in the *American Journal of Tropical Medicine* 14:127 (March) 1934. Histoplasmosis is apparently similar to kala azar, and sporadic cases have been observed in Minnesota by Watson and in Tennessee according to the quoted reference.

H. A. REIMANN, M.D., Minneapolis.

and Hospitals

COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral* (Group A and Group B candidates). San Antonio, Texas, Nov. 13-16. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written* (Group B candidates). The examination will be held in various cities of the United States and Canada, Nov. 3. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: San Antonio, Texas, Nov. 12; Philadelphia, June 10. Sec., Dr. William H. Wilder, 122 S. Michigan Blvd., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: San Antonio, Texas, Nov. 16. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

ARKANSAS: *Basic Science*. Little Rock, Nov. 5. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Regular*. Little Rock, Nov. 12. Sec., Dr. A. S. Buchanan, Prescott. *Elective*. Little Rock, Nov. 13. Sec., Dr. L. L. Marshall, 820 W. 14th St., Little Rock.

CALIFORNIA: Sacramento, Oct. 15-18. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Regular*. Hartford, Nov. 13-14. *Endorsement*. Hartford, Nov. 27. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homopathic*. New Haven, Nov. 13. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

FLORIDA: Tampa, Nov. 12-13. Sec., Dr. William M. Rowlett, Box 786, Tampa.

ILLINOIS: Chicago, Oct. 16-18. Superintendent of Registration, Department of Registration and Education, Mr. Eugene R. Schwartz, Springfield.

MAINE: Portland, Nov. 13-14. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton Jr., 192 State St., Portland.

MASSACHUSETTS: Boston, Nov. 13-15. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 144 State House, Boston.

MINNESOTA: Minneapolis, Oct. 16-18. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul.

MISSOURI: Kansas City, Oct. 24. State Health Commissioner, Dr. E. T. McGaugh, State Capitol Bldg., Jefferson City.

NEBRASKA: Lincoln, Nov. 22-23. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Carson City, Nov. 5. Sec., Dr. Edward E. Hamer, Carson City.

NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

OREGON: *Basic Science*. Portland, Nov. 17. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

WEST VIRGINIA: Martinsburg, Oct. 29-31. State Health Commissioner, Dr. Arthur E. McClue, Charleston.

Nebraska June Examination

Mrs. Clark Perkins, director, Bureau of Examining Boards, reports the written examination held in Omaha, June 8-9, 1934. The examination covered 10 subjects and included 91 questions. An average of 75 per cent was required to pass. Eighty-three candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
School of Medicine of the Division of the Biological Sciences		(1934)	1
Creighton University School of Medicine		(1933, 7), (1934, 16)	23
University of Nebraska College of Medicine		(1932), (1933, 4), (1934, 54)	59
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Michigan Medical School		(1929)	Michigan

One physician was licensed at a special examination held February 16. The following school was represented:

School	PASSED	Year Grad.
Northwestern University Medical School		(1933)

Two physicians were licensed by endorsement from February 24 to March 16. The following schools were represented.

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists		(1933)	N. B. M. Ex.
University of Oregon Medical School		(1930)	N. B. M. Ex.

Oklahoma June Reciprocity Report

Dr. J. M. Byrum, secretary, Board of Medical Examiners, reports 5 physicians licensed by reciprocity at the meeting held in Oklahoma City, June 6-7, 1934. The following schools were represented.

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine		(1933)	Kansas
State University of Iowa College of Medicine		(1929)	Iowa
University of Louisville School of Medicine		(1927)	Indiana
University of Nebraska College of Medicine		(1932)	Kansas
New York University, University and Bellevue Hospital Medical College		(1913)	New York

Book Notices

Applied Physiology. By Samson Wright, M.D., F.R.C.P., John Astor Professor of Physiology, University of London. Fifth edition. Cloth. Price, \$5.50. Pp. 604, with 195 illustrations. New York & London: Oxford University Press, 1934.

This textbook has received a well deserved popularity among practitioners of medicine. As Swale Vincent stated, "the day has gone by when a practitioner, however modest, can afford to declare that he has forgotten his physiology." This book is not a didactic presentation of physiology. The author's aim in preparing the original edition was to integrate physiology with clinical medicine. Special stress was laid on those functions which are commonly deranged in disease. Because of this and the skill and clarity with which it has been done, the book has been invaluable to students in medicine beyond their first two years and to those engaged in the practice of medicine. One would have great difficulty digging out facts and theories that are presented here in such a well correlated manner. The style and form of presentation make the book most engaging. It is simple and concise, yet almost every important aspect of applied physiology is discussed. In the various editions the author has made thorough revision to keep abreast of current developments in physiology and advances in clinical medicine. This edition is no exception. The most extensive revision has been in the physiology of the nervous, cardiovascular and endocrine systems. Among some of the features of the new edition that should interest practitioners are epinephrine secretion and blood pressure regulation; anatomy and physiology of the carotid sinus and body; mechanism of ischemic pain and its relation to angina pectoris; the pleural, pericardial and peritoneal sensibility after Capps and Morley; muscle tone and regulation of posture; the pituitary body, with an account of the follicle stimulating and luteinizing factors of anterior pituitary-like principle and their association with the menstrual function; dietetic and chemical control of erythropoiesis and the anemias; electrocardiographic records of direct stimulation of the human ventricle and necessity for reinterpretation of abnormal electrocardiograms in man; sympathectomy for vascular disorders in man; tissue oxidations, with concise accounts of cytochrome, Warburg's respiratory enzyme, indophenol oxidase and dehydrogenases, and many other subjects that have developed since their formal medical education. Bibliographic references enhance the value of this material and are well selected. An illustration of the author's desire to meet the needs of all classes of readers is the unique idea of printing in italics in the table of contents those parts of the subject which are wholly or mainly of clinical interest. This has been done for the student who has not had a background in clinical medicine and who might be preparing himself for an examination in didactic physiology. The feature has subtle pedagogic possibilities. The scholarly desire of the author to present facts has caused him to cull both the clinical and scientific American, French and English journals for current investigations. In spite of this new material and the addition of seventy new illustrations, the author has retained virtually the size of former editions. This has been possible only by critical editing and judicious deletions. This book should be the property of every medical student and practitioner. It was written for the specific needs of both, with a zealous desire to add to their knowledge and understanding of the physiology of disease. A book of this type is a distinct contribution to the progress of medicine.

Ocular Dioptrics and Lenses. By G. F. Alexander, M.B., C.M., Registrar, Ophthalmological Hospital of St. John, Jerusalem. Cloth. Price, \$4.75. Pp. 216, with 62 illustrations. Baltimore: William Wood & Company, 1934.

Here is a curious admixture of complex mathematical optics and sound refractive common sense. The author admits that the origin of the book lay in an endeavor to write an article on the why and wherefore of the change in the refractive strength of an ophthalmic lens on moving it forward from the eye. The elucidation of the subject led him far afield from the original object and there resulted page upon page of mathematical formulas that are beyond the comprehension of the average ophthalmologist. The phraseology employed is none

too happy, as may be exemplified in the second sentence of the book, which occupies twenty-five lines and contains forty-one commas, one colon, one semicolon, five parentheses, four i. e.'s and one final period. After ninety-six pages of formulas dealing with the laws of refraction and the optical constants of the eye, he proceeds to discuss the mechanism of accommodation. In this can be found many statements that are not universally accepted as yet; for example, "the hyaloid membrane surrounding the vitreous is highly elastic" and "the space between the zonule, the hyaloid, and the equator of the lens . . . is air tight." The ophthalmic physiologist will find many points in this chapter for the basis of delightful argumentation. From here on, the greater part of the book is devoted to various phases of clinical refraction and contains evidence of long, sound clinical experience. There is no bibliography but there is a fairly good index. The only illustrations are mathematical designs. The bookmaking, proofreading and printing are good. This is not a book for the beginner in ophthalmology but it can be read to advantage by one desiring further information in that ophthalmic essential, refraction.

Surgical Anatomy and Physiology. By Norman C. Lake, M.D., M.S., D.Sc., Senior Surgeon, Charing Cross Hospital, and C. Jennings Marshall, M.D., M.S., F.R.C.S., Surgeon, Charing Cross Hospital. Cloth. Price, 30/- Pp. 888, with 238 illustrations. London: H. K. Lewis & Co., Ltd., 1934.

The authors of this book have undertaken a tremendous task in attempting to present a treatise on surgical anatomy and physiology in one volume. However, they make no pretense at comprehensiveness on the physiologic aspect of the subjects covered but merely include an appreciable amount of physiology to round out the subject. One of the refreshing features of the book is the originality both in organization and in manner of presentation. The illustrations are adequate to clarify abstract descriptive material and the majority of them are original. The discussions are well balanced and show careful editing. In a book of this type there is always a danger of undue compression of certain descriptive detail at the expense of the uninformed reader. There is a surprising lack of it here. The application of anatomy to operative and pathologic surgery is considered under two headings, general and regional. For example, the alimentary canal is considered generally in the first section of the book with respect to development, supports, intestinal movements, radiography and bowel contents. Under the section of applied regional anatomy the various divisions of the alimentary canal are considered in detail, with ample treatment of physiology and pathology. As a concise and comprehensive treatment of surgical anatomy, this is an excellent textbook. It will be especially useful for the student and for those in their formative years of training, as an adjunct to more exhaustive textbooks.

Genealogy of Sex: Sex In Its Myriad Forms, From the One-Celled Animal to the Human Being. By Curt Thesing, M.D. Translated from the German by Eden and Cedar Paul. Introduction to the American edition by Smith Ely Jelliffe, M.D., Consulting Neurologist, Manhattan State Hospital and Kings Park State Hospital. Cloth. Price, \$5. Pp. 286, with 73 illustrations. New York: Emerson Books, Inc., 1934.

Dr. Thesing is a physician, zoologist and scientific writer of repute in Germany, author of numerous biologic works of both general and technical character. He has been director of the scientific division of the great publishing house of Teubner in Leipzig and a co-founder of the widely known periodical *Die Naturwissenschaften*. These qualifications peculiarly fit him to write the present work, which is a panorama of the development and diversifications of the reproductive function in the animal world. It is not a systematic unfolding of the successive stages of evolution traced up the ladder of life from ameba to man but rather the story of the many interesting and curious developments of sexual processes and mating behavior that have been evolved in various groups of animals from the lowest to the highest and from the simple to the complex. Some of these widely divergent and curious accomplishments of the sexual instinct serve to illumine the obscurer aspects of sexual behavior and abnormalities of sexual development in man. Among the topics discussed in the light of the broader comparative biologic consideration of sex among animals are the origin of sex, the sex cells and the sexual instincts, hermaphroditism and intersexes; the relation of environmental factors to sexual develop-

ment; the suppression of sexual development by parasitism; parasitic males in the marine worm *Bonellia*, in *Myzostoma*, a degenerate annelid living on crinoids, and in certain crustacea; the transformation of old hens into functioning cocks by glandular abnormalities; sexual dimorphism in sex cells and in adults; the phenomenon of dwarf males, structurally defective males, the diminution of the male ratio, and the ultimate extinction of the male sex, as in some rotifers in which no males have ever been found; the pairing of hermaphroditic animals such as snails; the cannibalistic behavior of the female spider, which eats the male, even before his purpose is accomplished; the influence of the sexual impulse on migration of fishes and birds; the relation of the lunar cycle to the spawning of the palolo worm of the coral reefs and of many other marine animals; the rhythms in man and woman of the ebb and flow of the sexual hormones; the strange behavior of the praying mantis, crayfishes, cuttle fishes, toads and Australian aborigines in copulation; the lures and stimuli favoring reproduction found among insects, birds, mammals, and aborigines such as color, odor, taste, tactile stimuli and fantastic behavior. The closing chapter is a review of the sexual habits of primitive peoples, largely drawn from Malinowski's researches in New Guinea.

The book is an interesting compilation of sex lore which should make even the calloused exclaim "Ain't nature wonderful."

Studien über die Permeabilität der Retina. Von Henry Key, Med. Lic. Inaugural Dissertation zur Erlangung der medizinischen Doktorwürde. Upsala. Sonderabdruck aus Acta Societatis Medicorum Suecane, Band LVIII, 1932. Paper. Pp. 82, with 29 illustrations. Stockholm: Isaac Marcus Boktryckeri-Aktiebolag, 1932.

This represents an extensive experimental work on the eyes of animals and man. The material was as fresh as possible in the human cases, as early as an hour after death. An elaborate technic was worked out for the study of the permeability of the choroid and retina as well as for the retina alone. The study was made first on the permeability of the tissues for water and for various alkaline and acid solutions as well as dyes. The permeability from within out, i. e., from retina toward sclera, as well as from without in, was estimated. The influence of various drugs was also studied. The author found that sodium iodide solution 0.04 per cent increased, atropine sulphate 1:50,000 reduced, and pilocarpine chloride and, even more, physostigmine salicylate increased the permeability of the retina for water. The significance of these experiments for the pathology of the eye may be mentioned. If in a detached retina the osmotic pressure of the subretinal fluid is greater than that of the vitreous, there may be some argument as to whether the fluid will pass from it through the retina. The fact that the retina is permeable to water in both directions will have an influence on the fluid exchange of the eyes. The new knowledge of the influence of drugs on retinal permeability may alter some ideas held about the actions of drugs in cases of glaucoma. The article contains sixty-five tables, thirteen illustrations and a comprehensive bibliography. The work is of special interest to the physiologist and the research worker in ophthalmology.

Diseases of the Eye. By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., Consulting Ophthalmic Surgeon, University College Hospital, London. Seventh edition. Cloth. Price, \$5.50. Pp. 693, with 374 illustrations. New York: Macmillan Company, 1934.

The last edition of this textbook appeared in 1930 and was reprinted in 1931. A review appeared in *THE JOURNAL*, March 22, 1930, page 891. That there is a demand for the book is evidenced by the necessity of a new edition after only four years, especially during these times of depression. The new edition contains sixteen more pages than its predecessor, the increment lying in additions to the existing text. No new chapters and no new illustrations have been added. The second chapter, on physiology, has been more or less rewritten, with especial attention paid to the balance of intra-ocular pressure and to the formation of the aqueous. The work of Duke-Elder is reflected in this. The remaining additions to the text have been more in the form of slight amplifications, such as the addition of about half a paragraph on the modern surgical treatment of detachment of the retina (with mental reservations as to results). The author is seemingly not thoroughly imbued

with the etiologic import of tuberculosis in diseases of the retina and uvea, although he begrudgingly mentions the possibility. The orthoptic treatment of squint, which is now attracting so much attention, is given but brief mention, but the pharmacopeia at the end of the book has been elaborated and rewritten and now is in a most useful form. Another appendix contains all the necessary information relative to the ocular requirements for admission to the various civil and military services. The opinions expressed in the review of 1930 still hold and again it must be emphasized that here is a moderate sized textbook for students and practitioners that is eminently worth while.

That Heart of Yours. By S. Calvin Smith, M.D., Sc.D. Cloth. Price, \$2. Pp. 212, with 6 illustrations. Philadelphia & London: J. B. Lippincott Company, 1934.

The increasing number of persons dying yearly from heart disease caused the medical profession to focus its attention on prevention. In an effort to reduce the morbidity and mortality, facts concerning the necessity of rest, prevention of infection and avoidance of strain were stressed to the public. While this type of education played an important part in the reduction of active heart disease, it raised a feeling of apprehension in some individuals. The profession has appreciated this. In a recent book the English cardiologist Sir Thomas Lewis devotes a section to the manner in which the physician should speak to his cardiac patient about his illness. Truth is the first essential, but it should be accompanied by encouragement and optimism. That, in substance, is the keynote of this book. The author has attempted to amplify and supplement the information the physician usually gives his heart patient. The book is clearly written in simple, understandable language. The optimism generated in the text is a product of modern study and observation. It is convincing as well as cheerful. Persons who have heart trouble, imagined or real, will benefit greatly by this book.

Tuberculosis in the Child and the Adult: A Discussion of Pathologic Anatomy, Pathologic Physiology, Immunology, Diagnosis and Treatment. By Francis Marion Pottenger, A.M., M.D., LL.D., Clinical Professor of Medicine (Department of Chest) University of Southern California, the School of Medicine. Cloth. Price, \$8.50. Pp. 611, with 85 illustrations. St. Louis: C. V. Mosby Company, 1934.

This book is recommended to students and practitioners. In it is assembled all present information on the subject of tuberculosis as it affects the child and adult. It is intelligently written, compact and liberally illustrated with roentgenograms and instructive diagrams. Topics of unusual interest are accompanied by references to the American and foreign literature. Much stress throughout the volume is placed on the allergic manifestations of tuberculosis, and the chapters on hypersensitivity, allergy and immunity are developed in great detail. Another hobby of the author's, "The Visceral Neurology of Tuberculosis," unfolds itself at length in an illustrated discussion of the part played by the vegetative nervous system in the production of signs and symptoms commonly seen in this disease. This exposition, showing how various organs of the body are reflexly affected by the action of toxins on the sympathetic nervous system, helps one to understand the pathologic physiology of pulmonary tuberculosis. The chapters devoted to childhood tuberculosis leave little unsaid on this important subject, especially as it concerns the relationship to adult tuberculosis. The pathology of tubercle, the evaluation of symptoms, signs and laboratory tests in diagnosis, and the various methods of choice in the treatment of different stages of the disease are discussed from every phase of present-day knowledge. This new textbook, while prejudiced along certain lines, reveals the author's thorough familiarity with his subject and is a worthy addition to any medical library.

Facies dolorosa; das schmerzenseiche Antlitz. Von Dr. H. Killian. Cloth. Price, 19.60 marks. Pp. 88, with 64 illustrations. Leipzig: Georg Thieme, 1934.

This is a collection of illustrations showing the facial appearances of people with various types of diseases. In his accompanying case histories the author classifies these facial appearances according to the associated mental processes. There is also an introductory sketch indicating the significance to be attached to studies of this type.

Medicolegal

Malpractice: Solution of Formaldehyde Mistakenly Used for Procaine Hydrochloride.—Prindle, a licensed physician, undertook in the Church of St. Matthew Mills Memorial Hospital to remove a cyst from the exterior wall of the plaintiff's abdomen. He directed a nurse, employed by the hospital, to prepare a procaine hydrochloride solution for use as a local anesthetic. Because of admitted negligence the nurse prepared a solution of formaldehyde, which the physician, believing it to be procaine, injected in the plaintiff's abdomen. He immediately noticed a violent reaction on the part of the patient, discovered the mistake, injected procaine and removed by incision, as far as possible, the area affected by the solution of formaldehyde. For the resulting damage the plaintiff sued the physician, the nurse and the hospital. The jury returned a verdict in favor of the plaintiff against the hospital for \$10,000 and against the nurse and physician for "\$ No dollars." The trial judge refused to direct the jury to reframe the verdict, and later, on motion of the hospital, entered a judgment in favor of the hospital notwithstanding the verdict of the jury, on the theory that the hospital was a charitable institution, had used due care in selection of its servants and was not, therefore, liable for the torts perpetrated by its servants on recipients of its benefits. The plaintiff then appealed to the Supreme Court of California.

The Supreme Court held that the trial court was without power to enter a judgment in favor of the hospital notwithstanding the verdict of the jury, inasmuch as the hospital had failed to move for a directed verdict at the close of the evidence. But because in the opinion of the court the verdict of the jury was too incomprehensible to support a judgment in favor of any party to the action, the Supreme Court ordered a new trial of the cause.

There was not a scintilla of evidence, the Supreme Court concluded, to support a verdict in favor of the nurse. She interposed no defense and made no denial to the allegations of the complaint that she was negligent. On the witness stand she admitted that she had neglected to read the label of the bottle containing solution of formaldehyde, which she used instead of procaine. It would be an anomaly, said the court, to hold the nurse to be free of negligence and to hold the hospital, whose agent she was, guilty of negligence.

In view of the retrial of the cause, the Supreme Court refused to pass on the liability of the physician under the evidence adduced at the trial.

As noted, the case was remanded to the trial court for a retrial of the cause.—*Hallinan v. Prindle (Calif.)*, 29 P. (2d) 202.

Dental Practice Acts: Revocation of License for Self-Laudatory Advertising.—The defendant, Waller, a licensed dentist, distributed circulars in which he claimed to be the only dentist in the Panhandle of Texas "doing Professional Denture work." The district court, Potter county, Texas, revoked Waller's license under a provision of the Texas dental practice act authorizing the revocation of a license if the licensee was guilty of "any deception or misrepresentation for the purpose of soliciting or obtaining business." Waller appealed to the court of civil appeals of Texas, Amarillo.

The judgment canceling Waller's license, said the court of civil appeals, rested on an accusation, charge, and evidence that may not be made the legal basis for depriving a citizen of Texas of the right to labor and enjoy the fruits of that labor in his chosen profession, even though all that was charged and proved against him be true. It was not claimed that any act of Waller in any way affected the health, safety, morals, comfort, or general welfare of the public, or any of its members; nor that Waller was not able to do proficiently and expertly everything that he said he could do; nor that anybody was misled or deceived to his injury, or could have been, by the statements made by Waller. Those statements, continued the court, amounted to no more than a claim that he was better equipped than his professional brethren to do a certain class

of dental work and that he was doing such work better than they. Being able to do precisely the character of work he advertised, questioned the court, who could be injured by the representation that he could do it better than others, unless it was his competitors who lost business to him by reason of his statements? If only his competitors would be thus affected, no contention could be made that legislative authority existed under the police power to cancel a professional license on any such narrow and selfish ground. The Texas court found itself in accord with the views expressed by the Supreme Court of Colorado in *Chenoweth v. State Board of Medical Examiners*, 57 Colo. 74, 141 P. 132, in which the Colorado court held unconstitutional a provision of the medical practice act of Colorado authorizing the revocation of a physician's license for "causing the publication and circulation of an advertisement relative to any disease of sexual organs," on the ground that the provision had no reasonable relation to the public health and comfort, or to the safety or welfare of society and hence could not be justified under the exercise of police power.

The provision of the dental practice act under consideration, as interpreted by the lower court, said the court of civil appeals, would permit the revocation of a license because of a simple misrepresentation to obtain business, even though such misrepresentation amounted to no more than "puffing one's wares" or "big talk," and even though such representations in no way affected adversely the health, morals, safety, or welfare of the public. The right to practice a profession has been called a property right, but it is more, continued the court. To obtain a license and proficiency requires the expenditure of money and years of preparation. Such right is the capital stock of its possessor from which dividends are expected sufficient to protect him from the infirmity of old age and to provide his family with the comforts of life. To cancel a professional license is to take away the entire capital stock of its possessor and to leave him in most instances the equivalent of a bankrupt. No legislature should be allowed to prescribe the infliction of such a penalty except by a law clear and unmistakable in its terms and which respects the interests of society and its members.

Because, concluded the court, no valid legal basis existed, under the accusatory portions of the complaint, for the judgment rendered by the trial court, that judgment was reversed and the cause remanded.—*Waller v. State (Texas)*, 68 S. W. (2d) 601.

Society Proceedings

COMING MEETINGS

- Academy of Physical Medicine, New York, Oct. 30-31. Dr. Arthur H. Ring, 163 Hillside Avenue, Arlington, Mass., Secretary.
- American College of Surgeons, Boston, Oct. 15-19. Dr. Franklin H. Martin, 40 East Erie Street, Chicago, Director-General.
- American Society of Tropical Medicine, San Antonio, Texas, November 14-16. Dr. Henry E. McLeney, Vanderbilt University School of Medicine, Nashville, Tenn., Secretary.
- Associated Anesthetists of the United States and Canada, Boston, Oct. 15-19. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary.
- Central Association of Obstetricians and Gynecologists, New Orleans, Nov. 1-3. Dr. Ralph A. Reis, 104 South Michigan Boulevard, Chicago, Secretary.
- Central Society for Clinical Research, Chicago, Nov. 2-3. Dr. Lawrence D. Thompson, 3720 Washington Boulevard, St. Louis, Secretary.
- Inter-State Postgraduate Medical Association of North America, Philadelphia, November 5-9. Dr. W. B. Peck, 27 East Stephenson Street, Freeport, Ill., Managing-Director.

- Pacific Coast Society of Obstetrics and Gynecology, Oakland and Del Monte, Calif., November 21-23. Dr. Clarence A. De Puy, 230 Grand Avenue, Oakland, Secretary.
- Radiological Society of North America, Memphis, Tenn., December 3-7. Dr. Donald S. Childs, 607 Medical Arts Building, Syracuse, N. Y., Secretary.
- Southern Medical Association, San Antonio, Texas, November 13-16. Mr. C. P. Loran, Empire Building, Birmingham, Ala., Secretary.
- Tri-States Medical Society of Texas, Louisiana and Arkansas, Shreveport, La., October 16-17. Dr. George P. Quinn, 427 Milam Street, Shreveport, Secretary.
- Western Surgical Association, St. Louis, December 7-8. Dr. Albert H. Montgomery, 122 South Michigan Boulevard, Chicago, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Migraine and Related Conditions.—Földes points out that visual disturbances and various nervous and psychic manifestations are not uncommon occurrences in attacks of migraine. Aside from migraine, however, paroxysms of headache, vomiting and visual disturbances are seen in other conditions, in particular in that form of uremia which has been variously termed the acute, convulsive or eclamptic uremia. This occurs in such forms of glomerulonephritis or nephrosis as are associated with visible retention of liquids; in other words, convulsive uremia occurs in the edematous forms of kidney disease. Therefore, the disturbances that regularly precede uremic convulsions or are manifested instead of the latter are caused by the same factors to which the convulsions are due. As to the pathogenesis of "convulsive uremia," there seems little doubt that it is the increased intracranial pressure caused by accumulation of fluids in the tissue of the brain and within the cavities of the brain which leads to convulsions. The theory of the pathogenesis of migraine presented is that attacks may occur simultaneously with changes in the weather. There is retention of liquid in the organism in the case of decreasing barometric pressure and this retention may lead to the development of a retentional type of attack; or the return of the barometric pressure to normal, following its drop, may lead to a release of previously retained liquid and consequently to a mobilizational type of migraine. The so-called common cold may be associated with attacks in sufferers from migraine, owing no doubt to the fact that almost all infectious diseases bring about retentions in the organism. The author applies his theory of the pathogenesis of migraine to its therapy; that is, the prevention of accumulations of liquid in the organism and the elimination of liquid previously accumulated. Prevention of water retention and elimination of water already accumulated should have a curative effect in the retentional type of migraine. In the mobilizational type, due to local accumulation of liquid in the brain which was previously retained in other parts of the body and then mobilized, prevention and elimination of retentions should similarly have a curative effect. The main principle on which such therapy should be constructed is that of the utilization of

food substances whose action is antiretentional and the restriction of food substances the action of which is retentional; that is, an antiretentional diet. Good results have been obtained in thirty cases of migraine with the antiretentional diet.

Gastric Motility Under Low Oxygen Pressures.—The experimental work of Van Lier on dogs emphasizes the importance of prescribing easily digestible food and food that will leave the stomach quickly in cases of disease associated with anoxemia. Animals subjected to what may be termed moderate grades of anoxemia showed a delay of several hours in the emptying time of their stomachs.

Perirectal Streptococcal Cellulitis.—Hayes reports a case of perirectal streptococcal cellulitis in which the streptococci were carried into the perirectal tissues during an operation for hemorrhoids, either by trauma or by the needle. At the suggestion of a roentgenologist, treatment with x-rays was begun. The temperature dropped 2.4 degrees F. within twelve hours after the first roentgen treatment. In less than eighteen hours there was a profuse drainage of grayish white, sero-sanguineous material from the wounds on both sides of the anus. Subjectively the patient felt much better. On the next day and the day following she was given further roentgen treatments. During this time the wound drained profusely and the areas round the rectum softened rapidly. The dosage of x-rays was spark gap, 5 inches; milliamperes, 3; no filters; distance, 10 inches; time, three minutes. On the eve of the third day the patient's temperature became normal and did not go above 99 F. after this time. Subjectively she was well; the hardness about the rectum had disappeared entirely. The sinuses gradually dried up; there was no communication with the rectum, no resultant fistulas and only one small, draining sinus when she left the hospital. A culture of the discharge from the wound, ten days after the cessation of the roentgen treatments, proved it to be entirely sterile.

Surgical Treatment of Empyema.—Frank emphasizes that operation for acute thoracic empyema is not an emergency and that aspiration or the closed operation should be employed in all cases in which the pleural fluid is not frank pus. Roentgen study of all pulmonary conditions is not an admission on the part of the practitioner of the lack of knowledge of symptoms and clinical signs but rather indicates his thoroughness in that he wants to see the existing pathology. Proper drainage regardless of the method employed will not only cure most cases of acute empyema but prevent chronic empyema. If chronic empyema does occur, plastic operation on the chest wall is followed by a lower mortality and better results than any other operation designed to obliterate the empyema cavity.

Treatment of Superficial Granulating Wounds.—Cannaday recommends for routine use a light, mouse-proof wire mesh and adhesive plaster in the treatment of wounds of a superficial nature. From this a screen or framework may be devised to be applied about the average wound so as to protect it from the traumatism incident to dressing contacts, clothing and other objects. This screen wire is cut to the size necessary to make an adequate shield over the wound. The edges are bound with strips of adhesive plaster and shaped so as to fit about the wound. Sometimes the edges of the screen or shield are elevated by placing a narrow runner of felt under each side of it. For the protection of a lacerated wound of the finger, an efficient screen may be made by encircling the finger with the wire mesh and holding it away from the tender, unhealed area by a felt support. In many instances raw areas so treated will heal in contradistinction to others that have been assiduously dressed day after day without apparent diminution in the size of the wound. The author has observed not a few instances of small unhealed areas that had resisted dressings of the conventional type over a period of six weeks or two months or longer, that did heal promptly after a short course of exposure to open air, sunlight or various electric lights advocated for this purpose. The application of heat, as by sunshine or lamp, presumably in part promotes healing by the improvement of circulation as well as by the drying of the skin. The position of the part involved often plays a large part in regard to the behavior of the case. The leg ulcer, waterlogged and edematous, makes slow, if any, gains while in the passive and dependent position. Periods of active exercise, alternating with rest in bed with the part elevated, are more likely to bring about improvement.

Leukocyte Counts During Pneumothorax Treatment.

Deegan used the interpretations of Medlar in studying the leukocyte count in fifty-two cases of far advanced pulmonary tuberculosis subjected to artificial pneumothorax treatment and other forms of collapse therapy in which the collapsed lung was allowed to expand subsequently. Twenty-five cases were classified as clinically arrested on discharge: in nine instances the initial septic type of blood picture changed to nonseptic, in two a hyperplastic type of blood picture was assumed, and in ten the blood picture showed a persistent septic type which, however, became less septic under treatment. One patient discharged as clinically arrested maintained an elevated septic type of blood count throughout the period of observation, although the clinical state was strikingly improved. In three cases which presented the septic type of blood count persistently in contrast to marked clinical and roentgenologic improvement it was felt that factors other than tuberculosis might possibly be influencing the blood picture. Six cases were discharged as clinically improved with the blood picture in agreement with their progress. Ten cases are classified as unimproved; all of them maintain a septic type of blood picture and, clinically, are stationary or retrogressing. Eleven patients died following the unsuccessful course of artificial pneumothorax therapy. In several instances in which there were chronic infections together with the tuberculosis, the blood picture was found to be septic in type, and it was thought that the intercurrent infection rather than tuberculosis was the cause of the persistent septic blood picture, as the patients were able to resume work and have remained relatively asymptomatic since discharge. The authors consider the Medlar interpretation of blood counts in cases of far advanced pulmonary tuberculosis subjected to collapse therapy a valuable guide in the clinical administration and control of these patients.

Pulmonary Aspergillosis and Bronchial Carcinoma.

Kampmeier and Black report a case of aspergillosis that occurred in the presence of a bronchial carcinoma. They made the diagnosis, tentatively at first, on the history and physical examination. However, some doubt was cast by the constant presence of the aspergillus in the sputum without tubercle bacilli. The roentgen shadow in the left lower lobe could not be satisfactorily explained on the basis of bronchogenic malignant tumor as could the hilus shadow, which was compatible with such a diagnosis. The fact that the shadow of the lower lobe cleared a great deal by the use of potassium iodide also was confusing. High voltage roentgen therapy was used over the hilus, however. Giese saw the patient in consultation and committed himself to a diagnosis of malignant tumor. Because of retention of secretion due to the neo-

plasm, the fungus probably had a good medium for growth. Whether the organism was a factor in the production of symptoms, and whether it aided in the destruction of tissue in the carcinomatous area is a matter for speculation.

Effect of Viosterol on Tuberculous Children.—Poncher and Gasul gave fifty-nine children, all contacts with tuberculosis and showing at least a definitely positive tuberculin reaction, a daily dose of 150 and 300 drops (10 and 20 cc.) of viosterol for four and three months respectively. The dosage of viosterol did not appear to have any definite effect on the course of the tuberculous process. Hypercalcemia was not produced. The authors feel that the use of relatively large therapeutic doses of viosterol administered over a long time to patients having tuberculosis is not favorable. Despite the failure to produce a definite hypercalcemia it was their impression that fluctuation in the weight curve (increase on the 150 drops of viosterol and decrease on the 300) that occurred is an undesirable effect. It may be that the administration of a larger dose for a short period will obviate this difficulty. When hypercalcemia is produced, symptoms such as anorexia and muscular weakness occur. While these symptoms disappear when viosterol is discontinued the desirability of hypercalcemia with such symptoms, even as temporary sequelae, is open to question. All patients, however, gained weight when viosterol was discontinued and this gain was much more pronounced than during the period when 150 drops of viosterol was administered.

Myositis Ossificans in Ligamentum Nuchae.—Thomson reports two cases of myositis ossificans circumscripta. Neither of the patients (men) gave a history of any direct injury. Both patients complained of the sensation of a lump near the base of the back of the neck, which seemed to come out, then disappeared and was not in itself painful except on pressure or manipulation, at which time it caused a "sickish feeling," slight nausea, shortness of breath and light headedness. Throwing the head backward, driving a car, going over bumps and wearing a stiff tight collar aggravated the symptoms. The

one patient who recognized the possibilities of surgical relief is now rehabilitated in his profession; the other died of other causes. No other evidence of myositis ossificans was found in either of these patients. The fact that these osteomatous bodies occurred in the collar line of the neck and the absence of a history of acute trauma would lead one to the conclusion that possibly the continuous irritation of a tight or stiff collar band or collar button might be the etiologic factor causing this condition. The author believes that, if his deduction is correct, these two cases may be classified as myositis ossificans circumscripta. A rather extensive search of the literature has not revealed any similar cases of muscular osteomas in the region of the ligamentum nuchae, except in young persons severely afflicted with the progressive type of myositis ossificans. Recalling the postmortem observations of the fatal case a year later gave the author the clue to the diagnosis of the other case cited; and the gratifying results of the operative removal of the osteomatous bodies, he believes, justifies his report. Perhaps these two cases are not sufficiently significant to warrant the suggestion that possibly roentgen examination of patients suffering similar symptoms might reveal osteomas. The author points out that the marked similarity between these bodies and those seen in hypertrophic (osteo-arthritis) arthritis cannot be overlooked, nor can it be entirely ruled out, as the calcareous deposits of the two conditions are similar. However, the lack of roentgen evidence of arthritis in the patient operated on and the lack of postmortem evidence of hypertrophic arthritis in the patient who died rather indicate that these are osteomas of myositis ossificans circumscripta.

Subtotal Bilateral Suprarenalectomy for Hypersuprarenalism.—DeCourcy recommends subtotal suprarenalectomy for the relief and cure of essential hypertension, based on the hypothesis that the cause of this condition lies in a hyperplasia of the medullary tissue of the suprarenals under constant sympathetic stimulation, resulting in the secretion of excessive amounts of epinephrine into the blood stream. The operation of subtotal suprarenalectomy, as performed by him, consists in the removal of from two thirds to three fourths of each suprarenal. It is done in two stages, with an interval of about two weeks between operations. The portion removed includes both medulla and cortex and is taken from the part of the organ remote from the entrance of the blood vessels. The approach is made from the back through a kidney incision, the kidney being held down with a special retractor. The suprarenal must be recognized and stripped clean of all fat and overlying structures. The portion to be removed is then clamped and excised, the raw surface being covered with a continuous chromic suture. Spinal anesthesia is employed and the blood pressure is watched closely throughout the entire operation. If the fall is more than anticipated, epinephrine is given promptly and intravenous saline solution with epinephrine should be ready in case of collapse. These patients, however, seem to tolerate spinal anesthesia very well. It is now about four months since the author has performed the first operation. He has operated on eight patients, doing sixteen operations. In every case the patients operated on have been improved; that is, the symptoms of hypertension have disappeared. The blood pressure has remained lowered in every case, the average drop and maintenance having been from 70 to 90 points systolic and from 40 to 50 points diastolic.

Overpull During the Treatment of Fractures.—Blum's study of twenty-three cases of overpull in fractures of the shafts of long bones reveals this condition to be a serious one by reason of an associated marked delay in healing, a higher incidence of necessary operative procedures and an increased time of hospitalization. It usually occurs in the first few hours and days following the institution of effective traction and, as a rule, is not successfully corrected by simple diminution of the tractive force. The prevention of overpull is of more efficacy in avoiding the untoward sequelae than is its treatment. This can be accomplished only by more thorough analysis of all the factors involved in each individual patient before ordering the type and amount of traction to be applied. In view of the widespread employment of the traction-suspension method in the treatment of fractures, the seriousness of this complication renders it worthy of consideration.

Leukocytosis in Chronic Pulmonary Tuberculosis.—Elrick points out that a review of the literature casts doubt on the correctness of the frequently held theory that leukocytosis in pulmonary tuberculosis is always due to a mixed infection with pyogenic organisms. The total leukocyte count, on the average, is lowest in incipient cases of tuberculosis and highest in far advanced cases. There are numerous individual cases that are exceptions to this rule, however. Leukocytosis is rare in uncomplicated minimal or moderately advanced tuberculosis, but fairly common in far advanced cases. In a study of one total leukocyte count in each of 229 unselected cases of far advanced chronic pulmonary tuberculosis without complications, the author observed a count of more than 12,000 in 24 per cent, and occasionally the count was as high as 20,000 or 25,000. The highest counts occurred in cases in which cavities had formed. That tuberculosis may cause a leukocytosis is an important fact to keep in mind when interpreting the significance of a high white blood cell count in a suspected acute surgical condition of the abdomen in a tuberculous patient.

Carcinoma of Cervix Uteri and Pregnancy.—Miller reports a case of carcinoma of the cervix uteri with a pregnancy of eight months. In its treatment, classic cesarean section was followed by immediate Wertheim hysterectomy under spinal anesthesia. Before the anesthetic was given the vagina was cleansed as carefully as possible, dried and filled with 4 per cent mercurochrome gauze. It was evident that the cervix was infected not only by necrosis of the carcinoma but also because of a biopsy wound, so the author planned to remove the fetus by fundal incision and leave the placenta in the uterus during hysterectomy. It was impossible to carry out this plan, for the placenta was implanted on the anterior wall and had to be removed. However, he was enabled to remove the placenta, cutting the membranes free and leaving them in situ. When the sutured fundus was opened later in the laboratory, the internal os was found to be covered entirely by membranes. Hemolytic streptococcus and Staphylococcus aureus were found on culture taken under the membranes at the internal os. The size of the cervix made any radical parametrial dissection not only inadvisable but impossible. Once the uterosacral ligaments were cut as far back as clamps could be placed, the uterus became mobilized. Dissection of from 3 to 4 inches of ureter was necessary and not unusually difficult and the vaginal clamps could be placed with ease. The patient stood the operation well, and healing ensued without infection. During the second week she suffered from cystitis and pyelitis and has made a slow convalescence. She is to receive high voltage roentgen therapy as soon as she can be transported. The baby weighed 5 pounds 5 ounces (2,400 Gm.) at birth and has gained normally on artificial feeding.

Nephritis Complicating Impetigo.—Sutton discusses five cases of acute nephritis which suggest that impetigo may have been the etiologic agent of nephritis. Nephritis did not occur in any of these cases until the impetigo had been established, and the impetiginous symptoms were the only ones complained of at the time of the beginning of the nephritis. During the period in which these five cases were admitted to the hospital,

thirteen other cases were diagnosed as acute nephritis, in which tonsillitis or some other condition was considered the etiologic agent. Acute nephritis in children is usually attributed to infections. Whether it is due to bacteria that act directly on the kidney or their toxins carried there by the blood stream has not been determined definitely. The author's five cases of acute nephritis, accompanied by impetigo, which occurred during a period of two years, comprised 28 per cent of the nephritic cases admitted to his clinic during this period and he reports them for the purpose of stressing the fact that impetigo, or the so-called dew-boils infection, which is frequent in the South, should not be taken lightly. This disease may be followed by complications.

Abdominal Surgery in Children.—Horsley emphasizes the point that the treatment of surgical conditions in children is not merely an adjustment of surgical principles and technic to a small scale. The child cannot be treated as a small adult. Increased and unstable metabolism in children incidental to normal growth renders them more liable to a violent reaction from a slight cause and makes disease sudden in onset and intense in symptoms. Moreover, symptoms are not limited to any particular region as in adults. The younger the child the more apt is the disease to manifest itself in generalized constitutional expressions rather than in focal signs and symptoms. Myers states that infants require much more water per pound of body weight than adults and that the loss of 10 per cent of the fluids of the body is grave and 20 per cent usually fatal. Surgical shock is easily caused and hemorrhage poorly borne, because the proportion of blood to body weight in a child is 1:20 as compared to 1:13 in an adult. Hence, narrower margins of safety in surgery of infants and children demand special attention and preparation. Pediatric surgery must be gentle, rapid and skilful. In infants and children the abdomen is normally large in proportion to the whole body and appears more so because of the small size of the pelvis and thorax. The abdomen contains not only the organs found in the adult but also the bladder and upper end of the rectum.

Postoperative Vomiting.—Smith observed that the use of 2 ounces (60 cc.) of dextrose orally three hours and 5 units of insulin half an hour before operation, and the repetition of the dose of insulin when the patient is returned to the ward and 4 ounces (120 cc.) of dextrose by rectum every four or five hours reduced the serious type of vomiting from 26 to 12.5 per cent in major and from 9.7 to 1.2 per cent in minor operations. His results in a series of 153 cases leave no doubt that in cases in which ether is used there is no way of controlling postoperative sickness except in a small proportion of cases, for which the cause must be looked for elsewhere than in pancreatic dysfunction. Provided that a good brand of ether is used, the particular make has little or no effect on postanesthetic vomiting. It is unjustifiable to use other than some form of purified ether. Morphine and atropine given in the usual way cannot be improved on. In insulin there is a real advance in prevention and treatment of postanesthetic toxemia and one that deserves wider recognition than it has at present.

Association Between Neurosyphilis and Cardiovascular Syphilis.—Healey points out that the figures obtained in a series of cases examined at a mental hospital show a much higher proportion of cardiovascular syphilis in cases of neurosyphilis than any yet reported. Cases of dementia paralytica sent to a mental hospital are advanced and therefore such a close correlation between neurosyphilis and cardiosyphilis is to be expected. The general conclusion to be drawn is that syphilis affects the whole body more commonly than is supposed; it supports the contention of Warthin that spirochetes will be found in every organ of the body in a syphilitic patient. It also supports the view that dementia paralytica is an active syphilitic infection and not a parasymphilitic process. The incidence of cardiovascular syphilis in association with neurosyphilis and mental disease is of immense importance from the point of view of treatment by induced malaria. In the early years of this treatment many patients died suddenly during or just after their pyrexial course, no clinical evidence of aortic disease having been found. It was taught that the clinical diagnosis of the nervous lesions was predominantly in the fourth decade and that of the cardiac lesions in the fifth decade, but in mental hospital work the two kinds of disease occur together in the fourth and fifth decades. Which lesion will be noted first depends partly on the severity of the separate lesions and also on the relative sensitivity of the two systems in the patient. Thus the make-up of the patient from both the physi-

cal and mental angles determines this issue. Ernest Jones has demonstrated that certain people have undue sensitivity of their internal organs, and, if this state is well marked, hypochondriac symptoms will result. These psychasthenic people, when infected with syphilis, complain of the lesions according to the more sensitive system, and thus the diagnosis is determined to a cardiac or a nervous state. In general one would expect an earlier outcry on the part of the nervous system, as it shows a more sensitive reaction to disease. In his series the author has found cases of fulminating dementia paralytica with pronounced cardiovascular changes within a decade of the initial infection. It is certain that patients who had short courses of arsphenamine treatment relapsed sooner than those treated with long courses of mercury. The latent period averages about ten years with arsphenamine treatment and twenty years with mercurial treatment. The author believes that it is likely that the spirochetal infection lies latent in the main lymph nodes and that at the end of the incubation period for the cardiac and nervous lesions, for some reason at present unknown, the infection flares up again and attacks the vital organs. It is known that the posterior cervical glands are affected markedly in secondary syphilis, and the author suggests that the spirochetes, lying latent in these glands, ascend into the spinal canal and cranial cavity and so cause syphilis of the spinal cord and brain.

Pentnucleotide Treatment of Agranulocytic Angina.—Wilkinson and Israëls report a case presenting the typical features of agranulocytic angina: rapid onset, lesions of the mouth, low pathogenicity of organisms isolated from these lesions and a myelocytic response following pentnucleotide therapy. In such cases the question arises as to whether recovery is due to the therapeutic agent employed or whether it is a spontaneous recovery. Before nuclein therapy, agranulocytic angina seems nearly always to have ended fatally. Jackson and his associates and Reznikoff have reported a considerable proportion of successes with nuclein therapy. There therefore seems to be definite ground for attributing the recovery of most of these cases to the nuclein preparation employed. The evidence of regeneration of the myelopoietic tissues as shown by the myelocytic response favors the view that agranulocytic angina is primarily a marrow dyscrasia and that the symptoms of the mouth are secondary in nature. Agranulocytosis may, however, also occur as an event in a long illness, as in the case of Fairley and Scott. In these cases the prognosis is of necessity less favorable. Madison and Squier have recently reported cases of agranulocytosis which they attribute to poisoning with amidopyrine, either alone or in combination with a barbiturate. Their observations provide further support for the hypothesis that the condition of the marrow is primary. In the case presented, neither of these drugs had been given. This patient was menstruating at the time of onset of the agranulocytosis. Thompson noticed that the onset of agranulocytosis in the majority of the women patients under his care corresponded with the commencement of their menstrual periods; whether this is purely coincidental or has a definite etiologic meaning is not at present known.

- *Abdominal Tympany in Subperitoneal Hemorrhages. C. Lenormant and G. Cordier.—p. 1257.
*Clinical Value of Gastric Chromoscopy. S. Zibalis.—p. 1260.

Tympany in Subperitoneal Hemorrhages.—Lenormant and Cordier report two cases of diffuse abdominal tympany following injury accompanied by subperitoneal hemorrhage. In its extreme form this can show the true picture of paralytic ileus. In the first case there was a history of renal contusion with massive hemorrhage but not necessitating surgical intervention. Generalized tympany and meteorism followed for about six days, with arrest of fecal material and gas for three. In the second case the abdominal symptoms followed bilateral fractures of the anterior lateral quadrant of the pelvis. The abdominal syndrome of ileus appeared, with diffuse abdominal tympany and without organic peritoneal or pelvic lesion, but due solely to irritation of the region by abundant hematoma of the space of Retzius. They recognize that the theory of the explanation which they advance is as yet insufficiently demonstrated. Thus a violent contusion affecting a sensitive zone of the anterior peritoneum produces a contraction. These are the contractions observed in intraperitoneal hemorrhages of the splenic ruptures. If the irritation caused by the blood is on a less excitable zone such as the posterior, the preperitoneal or the pelvic peritoneum, the result is as if the excitation remained below the threshold necessary to produce a medullary reflex. The sympathetic alone responds with intestinal distention and its clinical sign of tympany. If the hemorrhage ceases, the excitation stops and the meteorism disappears. If it persists or especially if an added irritative factor such as a blood clot occurs, the picture of an ileus or a parietal defense response appears.

Value of Gastric Chromoscopy.—In an attempt to determine whether gastric chromoscopy can replace the usual gastric test meal analysis, Zibalis examined a number of patients by both methods. His technic is as follows: After the patient has fasted for twelve hours, Einhorn's sound is introduced into the stomach; then, after the extraction of a sufficient quantity of fluid to titrate the fasting acidity, 5 cc. of a 1:100 solution of neutral red is injected in the buttocks. After the injection a small amount of gastric secretion is removed each minute and the time noted between the injection and the appearance of the first rose drops of gastric fluid. That is the chromoscopic time. Then the patient is given the alcohol test meal by sound (300 cc. of a 5 per cent solution of alcohol). Every thirty minutes some fluid is removed and titrated in the usual way. In this manner the results of the two examinations are obtained at the same sitting. The cases examined were divided into four groups according to the degree of gastric acidity: normal, hyperacidity, hypo-acidity, and anacidity. In five of the six with normal acidity the results of chromoscopy and gastric acidity concurred. If, however, the results of Held are admitted that a chromoscopic time of twenty-four minutes is

still normal, the six cases agreed. In the five examined cases of hypo-acidity, concordant results were obtained three times. In the ten cases of hyperacidity there was agreement in only three. Of the four cases of anacidity examined, none eliminated the dye in the stomach. The author believes that the discrepancy is due to secretion of mucus, which delays the elimination of the dye. He concludes that gastric chromoscopy cannot replace the examination of the gastric chemistry. Neutral red, however, remains a useful auxiliary in the functional examination of the stomach, especially in cases of anacidity.

Clinical Observations, Histologic and Macroscopic Lesions of Appendicitis in Disease Associations with Cholecystitis and Gastric and Duodenal Ulcer. G. G. D'Antona.—p. 677.

Renal Decapsulation and Periarterial Sympathectomy in Suppurative Nephritis.—Moriconi studied the effect of bilateral decapsulation of the kidney and of bilateral sympathectomy of the renal artery on the appearance and evolution of suppurative nephritis. The disease was artificially produced in dogs through intravenous injections of a culture of a strain of *Staphylococcus tropicus* in the kidney. The author observed a marked increase in the elimination of urine by the tenth day after operation, with concomitant hyperemia of the organ itself. The increased flow of urine and the accompanying hyperemia are of no value in the prevention of the experimentally produced bilateral suppurative nephritis. The advantages of mononephrectomy do not lie in the greater facility for elimination of micro-organisms through the increased excretion of urine or in accompanying hyperemia but in the increase of the local defense power. This increase likewise improves functional activity.

- *Nephrotomy Without Suture. C. M. Le Roy.—p. 393.
Cystic Intestinal Pneumatosis: Case. R. Memmi.—p. 408.
*Accessory Pancreas and Its Surgical Importance. L. Ugelli.—p. 424.

Nephrotomy Without Suture.—Le Roy made a full longitudinal incision on the convex side of the kidney of dogs and rabbits and opened up the whole renal pelvis. To obtain perfect hemostasis, he tied the two renal vessels together for from three to five minutes without applying any suture. In twelve animals subjected to bilateral nephrotomy without suture, cure was attained with only temporary hematuria in the first days following operation and without production of infarct so as to constitute a limited loss of substance with only temporary danger of functional impairment of the organ. The author states that nephrotomy without suture, as successfully carried out by Papin, is worthy of the greatest interest. It merits a wider application, since the points of suture of the kidney represent a frequent cause of late hemorrhages. In a dog with only one kidney after nephrectomy of a month's standing, nephrotomy without suture had to be abandoned because of persisting hemorrhages due to the abundant distribution of the blood vessels accompanying the compensatory hypertrophy of the organ.

Accessory Pancreas and Its Surgical Importance.—Ugelli presents the following observations based on 106 cases from the literature on accessory pancreas and on five cases personally observed. He states that the accessory pancreas is generally found in the thickness of the walls of the gastroenteric tube, from the cardia to the ileocecal valve. The stomach, the duodenum and the first loop of the jejunum were the most frequent sites of the accessory pancreas in the literature and in the author's observations. Accessory pancreas sometimes occurs in the intestinal diverticula. Seldom more than one accessory pancreas is found in a single patient. It may occur at any period of life. It is found equally well in men and in women. It is always congenital and may be associated with other congenital malformations. The nodule of the accessory pancreas is small and hard. Its histologic structure is similar to normal pancreatic tissue but may have only

glandular acini, or typical centro-acinous cells, or islets of Langerhans and excretory conduits. It is generally agreed that the accessory pancreas has both internal and external secretion. Little functional value is attributed to this secretion. The accessory pancreas may be the seat of disease processes involving the principal gland, such as acute necrosis, abscess, chronic inflammation, cystic degeneration, and tumors benign and malignant. In most cases the accessory pancreas is latent and is discovered only at operation or necropsy. Other cases present epigastric pains with frequent radiations to the right hypochondrium, symptoms of biliary calculosis and loss of weight. The only method of treatment is surgical intervention. The author concludes that this anomaly is not as rare as is generally believed and that it constitutes a frequent disorder capable of determining various disease symptoms and grave complications.

Tuberculous Granuloma with Buccopharyngolaryngeal Predominance: Case. C. A. Videla and J. Peroncini.—p. 1546.

Normal Phenolemia.—Castex and Arnaudo conclude that the normal concentration of phenols in the blood either is constant or shows but small variations. Normal persons receiving an atoxic diet show, as a rule, lower figures of phenolemia than those of normal persons who receive meat in their diet. The figures of phenols in the blood of normal persons frequently, although not constantly, run parallel to those of urea in the blood. Under normal conditions the elimination of large amounts of phenols does not modify the figures of phenolemia. The values of phenoluria cannot be determined by those of phenolemia in normal persons. Conjugated phenols in small amounts are constantly in the normal blood. At certain times they cannot be found in the blood, although they exist in large amounts in the urine. By using the Theis and Benedict method for the determination of phenols in the arterial and venous blood, no variations between the arterial and the venous phenolemia can be observed. While reporting the figures of phenolemia, it is indispensable to specify both the method used in its determination and the diet received by the patient during the determinations. The following are admitted by the authors as normal values of phenolemia in normal man and by using the Theis and Benedict method: free phenols, from 1 to 1.3 mg., total phenols from 1.1 to 1.4 mg., and conjugated phenols from 0 to 0.3 mg. per hundred cubic centimeters of blood. The variations originating in the differences of alimentation are included within these limits.

Catalytic Property of Blood of Children.—Török and Neufeld review former studies on the catalytic property of the blood of adults and children, pointing out that the condition of the liver, the endocrine system, nervous influences and the vitamins exert an influence on the catalytic properties of the blood. They show that attempts were made to use the catalase determination for clinical purposes. However, tests on children and nurslings revealed such great fluctuation under normal conditions that it seemed useless to determine the catalase content in pathologic conditions. In recent experiments, efforts were made to employ methods that avoid as much as possible all sources of error, but even in these the results were not entirely satisfactory. Consequently the authors decided to exclude also all external influences known to influence the catalytic properties of the blood. The tests were made only

on children who had been under their observation for some time and who were in bed the greatest part of the day, which largely eliminated the light factor and the influence of muscular exertion. The children received the same diet, and the withdrawal of blood was always done at the same room temperature and at the same time of the day (evening). The withdrawal was nearly always preceded by a fast of three hours, and only in a few control cases was the blood withdrawn half an hour after the meal. The tests were carried out during February and March, in a dark room and in weak illumination. The method employed was Bach-Levinger's titration procedure, in which the quantity of catalase is determined from the course of the reaction speed or from the velocity constant. In tests on adults this method had been employed by several investigators, but so far it had not been used on children. The authors, in comparing the results they obtained in children with those that had been observed in adults, find that the fluctuation is much greater in children than in adults. In healthy adults the velocity constant varied between 0.0184 and 0.0268, while in children the marginal values were 0.01600 and 0.04491. When the tests were repeated, more or less the same results were obtained, the greatest difference being 20 per cent. The authors conclude that their results are sufficiently exact to make their method available for experimental purposes.

Practical Evaluation of Ninni's Experimental Tuberculosis in Children.—Mikulowski points out that while the subcutaneous or the intraperitoneal inoculation of guinea-pigs with material of suspected tuberculous infection reveals the presence of tubercle bacilli only after five or six weeks, Ninni's method, the injection into the cervical glands, provides the same information in from ten to twenty days. He determined the reliability of Ninni's method on thirty specimens of cerebrospinal fluid, ten exudates, five homogenized sputums and five specimens of pus. The specimens were centrifugated and 0.1 cc. was injected into the surgically exposed cervical glands of both sides of the animals. Then the wounds were sutured. From ten to twenty days later, the glands were taken out, crushed and examined for the presence of tubercle bacilli. The glands commence to become palpable two weeks after injection, and thereby they also reveal the presence of tubercle bacilli.

The Electrocardiograph and Resuscitation Possibilities.—Bruns observed in asphyxiated animals that the electrocardiograph still registered cardiac activity thirty minutes after pulsation and cardiac sounds had disappeared, and he thinks that the same is probably true in human subjects. Thus it is proved by electrocardiographic studies that resuscitation efforts should not cease when respiration and heart beats fail but should be continued until rigor mortis and death spots appear. The author shows that electrocardiography is of great value in estimating the efficacy of the various resuscitation methods, particularly the different forms of artificial respiration, the stimulants applied to the skin and the mucous membranes, and the various forms of medicinal and mechanical cardiac stimulants. He emphasizes that an artificial respiration which does not at the same time stimulate the cardiac activity is of no value. In experiments with a pulmotor the electrocardiogram revealed that the mere entrance and exit of the air mixture exerted no influence on the heart. Consequently the apparatus was changed so as to prolong the interval during which the air is withdrawn and to afford an opportunity to percuss, concuss and press the thorax without necessitating a reversing of the apparatus. The electrocardiogram revealed that every percussion or massage pressure on the heart produced electrical currents in the heart. The author concludes from this that every artificial respiration, even the one carried out with a pulmotor, must be supplemented by energetic heart massage.

The mechanical and chemical irritants applied to the skin and the mucous membrane of the apparently dead reach the respiratory, cardiac and vascular centers and stimulate their activity. However, some of these sensory stimulants, particularly when applied to the chest, back and arms, reach the sympathetic innervation of the heart by way of the sensory cutaneous nerves and by way of the communicating branches. To make this possible, it is of course necessary that these nerve channels are still functioning. This can be detected in the electrocardiogram. If the electrocardiogram reveals electric currents in response to mechanical or chemical irritants, the autonomic nervous system can still function. The author observed in the course of electrocardiographic studies that only in unconscious persons, in whom the corneal reflexes are still demonstrable and in whom there is still a slight respiratory and cardiac activity, the cutaneous and mucous membrane irritants are capable of reaching the vital centers in the medulla oblongata and in the heart itself. After the corneal reflexes have been abolished and after respiration and cardiac action have ceased, the function of the sympathetic and of the vagus has already ceased and the irritants applied to the skin or to the mucous membrane no longer have any effect.

Specificity of Spirochetal Extract in Syphilitic Changes in Cerebrospinal Fluid.—Marquardt mentions a previous report in which he could prove that the pallida antigen is more sensitive in the Wassermann test of the blood than are extracts of syphilitic liver, beef heart or cholesterol. He found also that the spirochetal extract is particularly sensitive in tests on the cerebrospinal fluid. However, it was not determined at the time whether the greater sensitivity was not perhaps at the expense of the specificity. Using a larger material, he has made comparative studies on 486 specimens of cerebrospinal fluid. He finds that the positive outcome of the Wassermann reaction, which is made with the spirochetal extract, indicates syphilis with great certainty. If increase in protein and in cell elements is lacking, and if the colloidal gold, mastic and Meinicke clarification reactions are negative, the Wassermann reaction with the spirochetal extract is negative just like the one made with the extract of syphilitic liver. In cases of syphilis with changes in the cerebrospinal fluid, the Wassermann reaction with the spirochetal extract surpasses in sensitivity the Wassermann reaction employing extract of syphilitic liver, as well as the protein and colloidal reactions, and it is at least as reliable as the clarification reaction of Meinicke.

Treatment of Scurvy by Parenteral Administration of Vitamin C.—Bank describes a severe case of dietary scurvy with ulcerative gingivitis, severe anemia, suffusions, constant increase in the temperature and psychic disturbances. Daily intravenous injections of 100 mg of l-ascorbic acid promptly improved the condition. The increase in temperature disappeared on the second day of this treatment. Comparison with other reports revealed that the parenteral administration of l-ascorbic acid greatly reduces the period of recovery. The author thinks that this parenteral method is advisable particularly in the severe cases, but also in patients in whom scurvy or prescurvy is accompanied by gastro-intestinal disturbances, such as subacid or anacid gastritis, in order to prevent chemical changes that might reduce the efficacy of ascorbic acid.

Demonstration of Insulin in Blood.—Boller and his associates succeeded in demonstrating by means of blood transfusions that the blood of persons without metabolic distur-

bances contains minimal amounts of insulin when the person is fasting, but larger amounts after a meal with a high carbohydrate content. Control experiments, in which insulin was administered intravenously, revealed that the quantities of insulin that appear in the blood of normal persons are comparatively small (at the most from 1 to 2 units in 100 cc of blood). The blood transfusion experiments revealed further that the blood of diabetic patients, who are susceptible to insulin, contains no insulin following a carbohydrate meal. Moreover, in severe diabetes, in which there exists a resistance to insulin, the blood has no or only slight amounts of insulin following a carbohydrate meal, and in some instances the blood from these persons even increases the blood sugar of the recipient.

Nature, Diagnosis and Treatment of Preeclampsia.—Heynemann maintains that eclampsia and preeclampsia do not differ in their essential nature but are the same, the differentiating sign being a single clinical symptom, the convulsions. The clinical difference is generally only one of degree. Formerly the diagnosis was based mainly on subjective symptoms, such as headache, visual disturbances, nausea vomiting dyspnea, asthma, accelerated breathing and increased depth of respiration. He thinks that headache is the most frequent and occasionally the only symptom and advises that headache occurring without fever, should be considered a preeclamptic symptom, unless some other cause can be found. He shows that disintegration of the blood (hemoglobinuria and hematuria) and development of hepatic disturbances (icterus and increased bilirubin content of the blood) indicate preeclampsia particularly in case of edema and renal changes. However the majority of cases of preeclampsia lack these symptoms. Changes in the fundus of the eye (form and size of vessels) are present in some patients. The results of vascular spasms are observable also in the capillaries of the nail groove but their utilization for the diagnosis of preeclampsia is possible only with certain limitations. The epinephrine probe test of Muck is nearly always positive, but, since it is frequently present in patients without eclampsia and preeclampsia its diagnostic significance in eclampsia is limited. Greater importance may be attached to the facial edema, for it is present in nearly all women with eclampsia and preeclampsia. Axious restlessness of parturient women is often the most prominent preeclamptic sign. The increase in the depth of respiration is likewise typical for preeclampsia. Then there is the reduced galvanic irritability of the median nerve. The increase in blood pressure is one of the most important signs because it is generally the earliest indication of a preeclamptic state. A decrease in the quantity of urine and a considerable increase in the protein content are also signs of a beginning eclampsia. In some instances a sudden impairment of the general condition is the only indication of preeclampsia. If this symptom appears, the possibility of vascular collapse, cardiac weakness, rupture of the uterus, internal hemorrhage or preeclampsia should be considered. Premature detachment of the placenta, in case of a normal site of attachment, is not always a sign of preeclampsia. The author points out that in cases with indefinite signs the diagnosis may be difficult, but he emphasizes that a too frequent diagnosis is less dangerous than the failure to recognize eclampsia. At the first appearance of preeclamptic symptoms, venesection should be done. The first withdrawal should not be less than from 300 to 500 cc. If after this the preeclamptic symptoms do not disappear, the venesection should be repeated, or delivery by cesarean section

should be done at once, provided forceps delivery or version is not feasible. If icterus, greatly increased bilirubin content of the blood, changes in the fundus of the eye and stupor indicate a serious condition, cesarean operation should be done at once. Hypertension as such does not necessitate abdominal delivery, but, if it persists in spite of treatment, prompt delivery is advisable. The author evaluates a number of medicinal preparations that have been recommended by different investigators. He shows that the use of most of them is not sufficiently well founded.

Pressure of Cutaneous Vessels in Patients with Preeclampsia.—Raisz and Hazay conducted their studies with the aid of Herzog's apparatus, which measures not the pressure in the capillaries but rather the resistance opposed by the cutaneous vessels to the blood entering from the arteries. They found that the pressure of the cutaneous vessels of healthy pregnant women does not differ from that of healthy nonpregnant women. In pregnant women with edema, it was found that the pressure of the cutaneous vessels is much lower than in healthy persons. Studies on women with preeclampsia and eclampsia, however, revealed a greatly increased pressure in the cutaneous vessels, and the authors show that the pressure in the cutaneous vessels is a more reliable indicator of an impending eclampsia than is arterial pressure, protein content of urine, extension of edema or the various subjective symptoms.

*Influence of Ovarian Hormone on Blood Pressure. S. Liebhart.—p. 1896.

Irradiation of Cancer of Uterine Cervix During Pregnancy.—Hofmann cites some results of the surgical treatment of cervical carcinoma during pregnancy and shows that they are satisfactory as far as the mother is concerned. The child, however, if not yet viable, must be sacrificed. In irradiation the greatest danger for the child lies in the possibility of impairment by the rays, which increases proportionately to the earliness of the pregnancy, because in the earlier stages of pregnancy the distance between the source of the rays and the embryo is still rather small, and even during the second half of pregnancy an impairment by rays cannot be entirely excluded. The danger of damage to the fetus increases with the quantity of rays and when a cervical application is made in addition to a vaginal one. The use of roentgen rays is much more dangerous than the use of radium rays. The mother is in danger because the irradiation may be followed by an abortion and this in turn by an infection. Moreover, the author cites a statistical report which proves that the permanent cures are only slightly more than half as frequent after irradiation as after surgical treatment, and he agrees with the statistician that differences in the results of the two methods are sufficiently great to conclude that irradiation is hardly ever justified. But he admits that there may be cases in which irradiation has to be tried. He describes such a case. A woman, aged 27, mother of one child, asked medical aid on account of a profuse vaginal discharge. It was found that she was pregnant in the fifth month and that an erosion on the cervix was cancerous. Since the woman rejected an operation and insisted on carrying the child to term, irradiation was decided on. Small doses of radium rays were applied in two sessions and roentgen irradiation was entirely dispensed with. The child was delivered spontaneously at the normal time and there were no puerperal complications. The child gave no indication of impairment by rays. Several months after delivery the cervix again showed an erosion, and the woman was again pregnant (second month). The author considers this new pregnancy worthy of note, because pregnancy is rare following irradiation of cervical carcinomas. The woman submitted to a vaginal amputation of the uterus. At

present, two and a half years after the radium treatment, both mother and child are doing well. That the subsequent extirpation of the uterus was justified was revealed by the histologic examination of the cervix, disclosing numerous metastases. This also proves the great danger of irradiation with insufficient doses. Moreover, the author concedes that two and a half years is not a sufficiently long period to arrive at a definite conclusion, and that, even if the favorable effect should persist, a single case would not disprove the contrary testimony of larger statistics.

Influence of Ovarian Hormone on Blood Pressure.—Liebhart made tests with various forms of ovarian hormone on more than 300 persons; men, girls of the prepuberal age, mature normal women, castrated women and women of the menopausal age. All forms of application were tried and the doses varied between 100 and 5,000 mouse units. The blood pressure values were determined with the Riva-Rocci apparatus. It was found that the follicular hormone reduces the blood pressure slowly. Tests were made also to compare the blood pressure reducing action of the follicular hormone with that of histamine, of eholine and of extracts of striated muscles and other organs. It was observed not only that the action mechanism of the ovarian hormone differs from that of other substances but that it is of a specific hormone nature. In further tests, the author studied the reaction of the sympathetic nervous system to the influence of the ovarian hormone. He reaches the conclusion that the blood pressure action of the follicular hormone, as well as of the other substances investigated, depends on a number of other factors that are determined by hormonal, nervous and constitutional influences. The author summarizes the results he obtained on the various groups of persons. He observed that the follicular hormone extract influenced the blood pressure of men and of boys, but that the change was considerably less than in women. The pressure changes in girls of the prepuberal age resemble those in men and boys. Tests on women revealed that the reduction in blood pressure, following administration of follicular hormone, is greatest in women entering the menopause. Most of these women had hypertension and the extent of the reduction was correspondingly more pronounced. The author gained the impression that after the administration of follicular hormone the blood pressure decreases proportionately to the deficiency in the ovarian function.

New Table for Anesthesia. O. Povlsen.—p. 899.

Weil's Disease. T. Madsen.—p. 900.

Bilirubin Tolerance Test.—From his results and comparison with the results of other liver function tests, Brøchner-Mortensen concludes that in its limited field of application the bilirubin tolerance test is a sensitive test of the liver function. While inapplicable in hepatic disorders with bilirubinuria, it is useful in the diagnosis of cirrhosis and in evaluation of the condition of the liver in chronic hepatitis and cholangitis and in examination of possible injury of the liver in infectious diseases and different disorders, such as diabetes, exophthalmic goiter and certain skin and brain disturbances. It may prove to be especially suitable for the investigation of possible lasting functional disorders of the liver following acute hepatitis.

THE FUNCTIONS OF THE FULL TIME PATHOLOGIST IN HOSPITALS

NICHOLAS M. ALTER, M.D.
JERSEY CITY, N. J.

The functions of the pathologist are but vaguely defined and understood. Since Virchow's first pathologic publications, about seventy-five years ago, the progress of medicine in general has been rapid. With this the functions of the pathologist have increased in scope and importance.

After the fundamental work of the great German pathologists Virchow and Cohnheim, pathologic anatomy was separated as a distinct branch of medical science. At first the pathologist, as "prosector," had a narrower field, confined mainly to the study of autopsy material. The rapidly progressing surgery, however, opened a new field of surgical pathology, thereby aiding the study of disease in vivo. The general advances of medicine at the same time made the pathologist an important adjunct in all lines of diagnostic work. This practical standpoint of diagnosis is responsible for increasing the importance of the laboratories beyond the scope of morphology. All branches of so-called clinical pathology (biochemistry, bacteriology, serology, hematology, animal experimentation) made rapid progress in developing diagnostic methods and have increased the usefulness of the pathologist as a diagnostician.

Such considerations are mainly responsible for the fact that the laboratories and the pathologist play an important rôle in the standardization of hospitals. Briefly expressed, the hospitals have the following functions: (1) to take care of patients, (2) to promote medical progress and (3) to elevate the educational standards of the medical profession. To comply with such requirements, the laboratories and the pathologist have a great responsibility. The important rôle of the pathologist is best defined by discussion of the following four functions: (1) as laboratory consultant, (2) as research consultant, (3) as scientific administrator and (4) as educational director.

LABORATORY CONSULTANT

The size and organization of the laboratories depends on the type and size of the hospital and on many other factors. The various branches of histopathology and clinical pathology require more or less technical personnel. These in turn need supervision and direction. This must be supplied by at least one physician-pathol-

ogist. This pathologist is the laboratory director and as such is necessarily the link between clinical and laboratory medicine. While even routine work, to constitute worth while relationship to clinical diagnosis, requires the special training of the biochemist and bacteriologist, the really proper field of the pathologist is tissue pathology.

In the first place the pathologist is responsible for the autopsy work. Only too often there are two indications for autopsy work in the hospitals: (1) the requirement of autopsies in not less than 15 per cent of deaths, for intern training; (2) to check the clinical diagnosis and determine the immediate cause of death. As a matter of fact, autopsy material offers a veritable treasure mine of medical knowledge. There will be a natural increase in the percentage of autopsies obtained if the value and use of the autopsies are demonstrated to the attending and resident staffs.

Remarks such as "What's the use of the autopsy, we know the patient had pneumonia" are quite common. The patient may have died of pneumonia but there may be, besides the various scientific aspects of this condition, a great many striking abnormalities in the other organs which are most instructive, demonstrating various phases of pathogenesis of many other diseases (coronary sclerosis and so on). Frequently autopsies are mistakenly limited to confirmation of the clinical diagnosis. Common remarks by clinicians or residents are also "We are interested only in the gall-bladder and liver" or "We do not care about the heart or brain." As a matter of fact the real results of the autopsies can be seen only after the coordination of all the gross and microscopic observations. Besides the vast pathologic aspect, the autopsies offer opportunity for normal anatomic, bacteriologic and surgical studies.

At this point emphasis has to be laid also on the technic and plan of autopsy work, not only for the success of scientific studies but to avoid justified antagonism on the part of the lay public and undertakers. Often utilization of autopsy work is limited to gross observations instead of extending it to various degrees of histologic studies. Various phases of this work have to be recorded by means of photomicrography, drawings and lantern slides. Such records are important not only as part of the hospital work but also from the standpoint of educational research and legal medicine. Gross and microscopic materials have great value as teaching material when used for meetings, demonstrations and permanent museum work. If properly studied and worked up, such material also suggests further experimental work. Surgical pathology is often also appreciated only so far as surgical diagnosis goes. The fact, however, is that surgical pathology affords opportunity to study various phases of the pathogenesis and course of diseases in vivo rather than the terminal

stages of autopsy observations. It offers the most stimulating teaching material not only for the education of the staff but also for the pathologist himself. It is granted, however, in regard to surgical pathology, that diagnostic work is of prime importance from the standpoint of the patient so far as prognosis and further treatment is concerned.

The judicious use of the frozen section method is helpful, but rapidity of diagnosis should not be emphasized at the expense of accuracy. Medicolegal questions not only necessitate accurate pathologic records but often require toxicologic examinations. Study of diseases naturally embraces pathology, bacteriology,

- III. Adaptation, modification, of new methods

serology, immunology and hematology in the closest coordination. For many routine examinations along these lines, technicians are relied on entirely. It is obvious that the methods of the technicians should be supervised by superior knowledge, which requires special training of the highest quality. This is best exemplified in relation to biochemistry. Many of the methods in blood chemistry (for example, urea determination by the Marshall method) are so simplified and standardized that technicians are capable of doing them, but no matter how simple any of them are the sources of error are innumerable. The greatest attention has to be paid to standards, which deteriorate in shorter or longer time and, even if new, require careful checking. Standardization and calibration need competent supervision. Most of the methods, moreover, require judicious adaptation. No technician would be expected to decide, for example, what kidney or liver function tests are generally reliable or most suited for certain clinical cases.

Finally, the pathologist will be called on to make interpretation of the results of laboratory examinations. His services are particularly helpful when consulted as to the choice of laboratory methods needed to build up the diagnosis. The necessity of adaptation and modification of new methods will be usually judged by the pathologist but often requires the highest skill, training and experience in the special lines (biochemistry, bacteriology and the like).

RESEARCH CONSULTANT

The pathologist is expected to be broadly trained in his knowledge of diseases; his knowledge must supplement that of the clinician; he must be able to correlate pathology and clinical medicine; he must know theories of pathogenesis and facts of prognosis; he must know the limits of certainty and the needs of future research. If all these things are true of him, he becomes thereby the most valuable of clinical and research consultants. For such scholarly attainment he has mainly two sources: (1) the practical study of material offered in the laboratory not only for diagnosis but also for self education; (2) literary studies. A reference library

is indispensable not only for the pathologist himself but also for the entire staff, and his advice is often sought. To follow foreign literature, knowledge of languages is of great importance in literary research.

As the pathologist has to be engaged in continuous studies of the current literature, it is essential that the library should be kept up to date. He needs and obtains much stimulation by personal contact with various scientific societies. In this way he brings to his associates knowledge gained from sources and views not ordinarily within reach of the clinicians. He is not only expected to follow the progress of new medical developments but to be capable of contributing to these developments himself by utilizing his own observations. Original observations may be based on morphologic studies or may be clinical, in which case the pathologist may serve as adviser or consultant. Clinicians and pathologists may also join as collaborators in such original work as involves laboratory and clinical methods.

In experimental work with animals the pathologist has to possess a great deal of special information concerning the type of animals, their anatomy, pathology and so on. The value of such animal experiments will depend on the knowledge, experience and judgment of the pathologist in regard to methods, results and their interpretations.

Following all the work of the various branches of the laboratories, the pathologist gains knowledge of practically the entire scientific material of the hospital. He is thereby in the best position to suggest problems to be worked up or subjects to be published. Of course, it is granted that the scientific material is available only if it has been systematically collected and arranged (museum, index of diseases, collection of lantern slides, photographs, drawings).

The pathologist is a useful consultant and critic in preparation of papers of the staff and offering material for even larger publications, as books.

SCIENTIFIC ADMINISTRATOR

As the chief full time scientist of the hospital, the pathologist is first of all a scientific consultant for the medical director or superintendent in scientific questions. His advice will be sought for in such scientific matters as records, mortality and hospital hygiene.

Hospital records, when completed, are great assets in a hospital. Records have to be built up as completely as possible not only with all the laboratory information but also with photographic illustrations and charts. Such records can afford a wealth of material for research work at a much later date. This may also acquire great importance from a legal standpoint and with systematic indexing can be the basis of accurate statistical studies.

The problems of hospital hygiene are too many to enumerate. The pathologist is obviously responsible for all questions in connection with the morgue. The periodic health examinations of the entire hospital

personnel should include laboratory work, throat cultures and stool cultures. Hospital planning and construction require special consideration from the standpoint of asepsis (operating room, operating material, nursery).

The question of epidemics is to be thought of from the standpoint of prevention as well as actual occurrence. Cases of contagious infections are often discovered in the laboratory.

The food supply requires the systematic supervision of the laboratory.

- II. Relation of pathologist to attending staff:
 1. Liaison officer between clinical and laboratory medicine
 2. Research and diagnostic consultant for patients
 3. Collaborator of papers of staff for publications and meetings
- III. Relation of pathologist to resident staff (supervising interns, curriculum besides laboratory training, and so on)

In the hospital organization the pathologist is in intimate contact with the attending and resident staff. He is the liaison officer between all branches of clinical and laboratory medicine. His various contacts are mentioned in other places of this paper, but emphasis has to be laid on his work in the operating room and on rounds, and also to his collaboration with the attending staff in all the research and diagnostic work and preparation of papers of the staff for publications and meetings. His relation to the resident staff is an intricate one. Besides the laboratory training during their curriculum, the resident staff is in continuous touch with the laboratory and under direct and indirect supervision of the pathologist. It would be a great loss to the efficiency of a hospital if the pathologist should be considered only as a "laboratory" man in charge of routine laboratory work. With all the work enumerated, the scientific advice of the pathologist has to have the weight of authority but should not be confused with executive authority of the head of the hospital.

EDUCATIONAL DIRECTOR

The laboratory has a share in the diagnosis of every hospital case. The laboratory material, whether it is purely morphologic (autopsies and surgical pathology) or from the other various branches of clinical pathology, lends itself for educational purposes. There is nothing more stimulating to medical thought than a well prepared clinical-pathologic presentation with definite laboratory data, including gross and microscopic material, roentgenograms and other clinical information. It provides a firm basis for discussion of diagnosis and treatment.

All this laboratory material, if properly worked up and collected, is available not merely for one occasion but permanently for demonstrations and systematic lectures. Gross pathologic material (from autopsies or surgery) is best preserved in a permanent museum. The microscopic work can be demonstrated by micro-projections or with lantern slides and photomicrographs. When photography is not suitable for

reproduction, drawings may be necessary. All this material, when properly collected and classified, may become useful for illustration of publications at a later date. The same applies to the material derived from the various branches of clinical pathology (gross and microscopic material, charts). Such work, first of all, adds to the education of the pathologist himself, continuously increasing his experience and improving his judgment. It serves similarly as a stimulus for the entire staff collectively and individually. Comparative studies of pathologic material and roentgenograms, of clinical, morphologic and chemical studies of various diseases (such as nephritis) are examples of the cooperation between the individual departments of the hospital and the laboratory.

For the practical education of interns and the resident staff, well organized laboratory work forms an indispensable and firm basis as a part of their hospital curriculum, and appreciation of the various uses of the laboratory should develop to the very end of their hospital service. The interns and resident staff play a major rôle in securing permission for autopsies. Enthusiastic cooperation can be obtained only by rewarding their troubles with demonstration of the value and use of the autopsies. The direct and indirect links between the interns and the laboratory are too many to enumerate.

The pathologist contributes in numerous capacities to the training of nurses. Both undergraduate and graduate nurses should know enough of the purpose and methods involved in common clinicolaboratory procedures to cooperate in handling patients properly to obtain the best results.

Although the hospital constitutes an educational center for its own medical staff, the profession of its vicinity has also a legitimate claim on it. It is again the pathologist, with his well arranged collections from all branches of laboratory material, who can be called

TABLE 4.—*Educational Director*

- V. Postgraduate teaching
 1. Special postgraduate courses
 2. Regular pathologic demonstrations
- VI. Education of public (lectures, demonstrations)

on to arrange or participate in shorter or longer post-graduate instruction courses.

As in large institutions there is a continuous flow of gross pathologic material (from autopsies and surgery), systematic pathologic demonstrations can be arranged by the pathologist for the hospital staff as well as for the outside profession all the year round.

Some problems of preventive medicine and public health (cancer, tuberculosis and other infectious diseases) can be coped with successfully only if every medical institution, with its pathologist and pathologic material, will be a permanent source of public enlightenment through lectures and demonstrations.

SUMMARY

All these may seem as a formidable array of functions. Still the possibilities for the pathologist are not nearly exhausted if he applies himself with wholehearted devotion to the service of the institution. Every phase of the hospital work is directly or indirectly and intimately connected with his work. Therefore, essential requirement of the pathologist is a tactful personality, as the harmonious cooperation of the entire hospital personnel is of prime importance for the success of the institution.

On the other hand, if the hospital wants to secure the benefit of the best services of the pathologist, it is under numerous obligations to him. First of all the pathologist has to have the authority and respect as the chief scientist of the institution. He is not only a man of special training but one engaged in continuous scientific pursuit of the various branches of exact sciences in relation to medicine. All the functions of the pathologist are not only too numerous but also time consuming.

In order that his work may be successful, he has to devote his undivided attention to the institution on a full time basis. To do his best the pathologist has to be freed from too many cumbersome outside interests, which he is sometimes forced to undertake to eke out his existence.

The hospital will be amply rewarded not only with high scientific standards, which is the pride of an institution, but by being able to offer the best possible care of the patients who come to it for diagnosis and treatment.

410 Fairmount Avenue.

ABSTRACT OF DISCUSSION

DR. WILLIAM CARPENTER MACCARTY, Rochester, Minn.: To live up to Dr. Alter's ideals, a pathologist would of necessity be a superman. He would have to be a tissue pathologist, bacteriologist, serologist, immunologist, protozoologist, chemist, somewhat of a clinician, super laboratory technician, toxicologist, hygienist, medicolegal expert, experimentalist, and in some hospitals a roentgenologist. Above all he would of necessity be an executive of no mean ability. When I first became a pathologist I was expected to do all of these things except roentgenology. I soon realized that no one man could master all these fields. I therefore suggested a division of responsibility, each division being placed in the hands of an expert. In a large institution is the only way the function of pathology can be carried out efficiently. The smaller hospitals for economic reasons will quite naturally have to be satisfied with lesser degrees of general expertness. Realization of this necessity has been responsible for the development of commercial or special independent laboratories, which serve a whole community. In laboratories that serve a greater number of physicians than can a small hospital, the financial returns permit greater division of function among technical experts who are supervised by an executive familiar with the various phases of this great field, which now has so many divisions. In our institution there are many independent subdivisions, each larger than the original department twenty-five years ago, and the members of one division are not and probably could not be trained to do the work of any other division. The directors of each subdivision would not consider themselves capable of assuming responsibility of any of the other subdivisions. I believe the term pathologist will eventually disappear as a designation for a specialist in medicine and will assume a broad significance, such as has the term philosopher. It probably will have no greater specificity and at the same time apply to individuals who deal with all abnormal states or phases of life, even including sociological abnormality. Dr. Alter's paper will serve, I hope, to impress on the general profession the great

changes that have occurred in scientific medicine in the last twenty-five years.

DR. NICHOLAS M. ALTER, Jersey City, N. J.: I agree with Dr. MacCarty that the pathologist is almost a superman. It is difficult to define pathology. The best definition is that it is a study of diseases. The study of diseases has progressed and widened enormously, and the pathologist as a full time scientist of the hospital is expected to know a great deal. The reason I brought this question up is that higher standards are wanted for those scientists who are called pathologists and more respect than most hospitals now give. Today hospitals are apt to employ pathologists who have very rudimentary experience. Higher standards will benefit both the pathologist and the hospital.

THE CAUSE OF DEATH IN
PNEUMONIA

HARLOW BROOKS, M.D.
NEW YORK

My purpose in this study was to investigate the immediate cause of death in pneumonia, both from a clinical and from an anatomic standpoint. The material consists of 200 consecutive cases of pneumonia, which were studied clinically and which finally came to autopsy in the Fourth Medical Service at Bellevue Hospital.

The autopsies were performed by various members of the pathologic staff under the chief pathologist, who has permitted me to utilize the material in this manner. The clinical studies were based on the usual records of the cases under the regular attending physicians and their associates of the division, with additional notes when possible of the immediate manner of death.

During the war as chief of medical service at the Camp Upton Base Hospital, as senior consultant in medicine to the Second Army, A. E. F., 1918-1919, and finally after the armistice attached to the army laboratory at Dijon, France, for this purpose, I made a study of this subject augmented by an analysis of the postmortem records of 5,000 fatal cases of war pneumonia in the American Expeditionary Forces. The summary of this study indicated that most of the patients dying from pneumonia in the American Expeditionary Forces during 1917-1919 did so with a terminal cardiac failure and a final dilatation of the right heart. I felt, however, that the prevalent type of pneumonia occurring in the army during this period was a special form and that conclusions deduced from this material do not fully pertain to the types of pneumonia usual in New York City and its environs. These data, therefore, are not considered in the present study, although observations then made on this enormous material cannot but influence one's point of view to some extent.

In the present series of 200 consecutive fatal cases, no differentiation has been attempted to segregate the various anatomic types of pneumonia, since the histologic process is essentially identical in all. The requirement has been that all should have had as their apparent etiologic factor one of the various forms of pneumococci. Nearly all these cases were typed, either from the blood or sputum ante or post mortem, but since so many forms of pneumococci are now recognized, though sometimes with difficulty, and since the bacterial type furnishes no apparent relationship to the

From the Fourth Medical Service, Bellevue Hospital.
Read before the Section on Practice of Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

manner of death or to the pathologic changes studied post mortem, no subclassification has been attempted.

The group comprised 174 males and 26 females. One patient was within the first decade, three were within the second decade, thirty-two were in the third decade, thirty-two were of the fourth decade, thirty-six were of the fifth, fifty-one were of the sixth, thirty-three were of the seventh, eleven were of the eighth, and one was of the ninth decade.

Clinical study of the manner of death from ward observation and from the histories and charts, with particular reference to the type of exitus, indicated the death to be due apparently to cardiac failure in seventy-seven instances. It is significant to note that at autopsy 116 cases showed definite chronic cardiac disease which clearly existed before the onset of the pneumonia. This high percentage may bear some possible relationship to predisposition to pneumonia or may indicate the decreased outlook which the subjects of chronic cardiac disease present against fatal termination in pneumonia. Seventy-three cases showed acute cardiac lesions which developed clearly during the disease and which played a very certain rôle in the termination by death. The heart was mentioned as normal, or entirely ignored among the factors concerned in death in but twenty-nine instances. Fourteen cases showed acute valvular endocarditis.

These data, I believe, substantiate the impression of most experienced clinicians that patients with pre-existing cardiac disease are particularly bad risks in pneumonia and that both clinical and pathologic observation confirms the commonly accepted conclusion that death occurs with greatest frequency with the clinical picture and the pathologic changes of heart failure.

No clinician of experience, however, can be blind to the fact that cardiac failure alone is not the sole factor in death in pneumonia from circulatory failure. Death from circulatory failure is often preceded by days, hours or moments of dilatation and congestion of the capillaries and veins, while the heart action itself is still apparently fairly maintained. There can be no question whatever that vasomotor paralysis of the superficial and deep capillary beds is a most important factor in the picture of circulatory collapse. One hundred and nine instances, inclusive of the seventy-seven cardiac cases cited, showed this type of circulatory failure. Definite and reasonably efficient methods exist for the support and maintenance of cardiac action, but there are all too few efficient means for the treatment of peripheral circulatory collapse. If these symptoms and signs are improved as by the action of solution of pituitary or epinephrine, with a resumption of relatively normal blood pressure and relief of capillary congestion, improvement in the status of the case follows in some instances. No amount of oxygen administration in any form appears either to obviate or to improve these conditions when they appear in failing cases of pneumonia.

It is universally recognized by practitioners that a positive blood culture in any bacterial type of pneumonia is one of the most serious, if not the most grave, prognostic signs that may appear in an early stage of pneumonia. This study fully confirms the general clinical impression that septicemia is in all probability the one most constant serious clinical sign of grave import.

In this series of 200 fatal cases, either positive blood cultures or definite pathologic signs of septicemia found at postmortem were shown in seventy-five cases. Clinical study of the charts confirms this conclusion fully.

Thus, fourteen cases showed active acute endocarditis, thirteen cases acute meningitis, twenty cases empyema, and six lung abscess. In many cases a septic type of temperature with profound toxemia even in the absence of confirmatory blood cultures appears to have precisely the same sinister prognostic weight as positive cultures.

I am of the opinion that the degree of sepsis present is the most significant factor in prognosis in the disease and that its presence is the most frequent basic cause of death. It was clinically or bacteriologically diagnosed as present in ninety of the 200 fatal cases. In septic cases, death may occur from terminal cardiac failure, from pulmonary changes or otherwise; the first mentioned manner of death, however, appears to preponderate in this series.

Meningitis has been found to be a frequent immediate cause of death in this group. Whenever it has appeared, it has been an index of sepsis. Its occurrence bears no relationship to the extent or location of the lung invasion, or apparently to the type of pneumococcus present. It was present as the dominant cause of death in thirteen instances in this series. It had been correctly diagnosed ante mortem in all cases. It has been the custom of many clinicians, myself among them, occasionally to recognize a clinical picture known as meningismus, a condition with sterile spinal fluid but with the clinical indications of cortical irritation. As a result of these studies I am convinced that there is no such condition as meningismus in pneumonia but that all instances so diagnosed are in reality cases of meningitis or of encephalitis. I believe however that in certain mild cases of these, recovery may occasionally, though rarely, occur. This statement will be disputed by some excellent and experienced authorities beyond doubt.

The degree in which anoxemia plays a dominant rôle in the immediate cause of death in pneumonia is exceedingly difficult to ascertain with any satisfactory degree of certainty. Accurate studies of this nature would as yet imply methods of such character as more or less seriously to hazard the welfare of the human patient. The mere chemical study of the blood furnishes very insufficient data for this purpose, and one probably can do little more in the ordinary clinical case than to study and attempt to estimate the value of oxygen administration to apparently moribund patients, just as one attempts to evaluate similar clinical methods for the relief of circulatory failure.

So far as my observations go, the extent of lung involvement is of but minor value as a prognostic factor in death in pneumonia. Thus, of the present group, fifty cases showed involvement of but a single lobe, in forty-two two lobes were invaded, in nineteen three, and in eighteen four or five lobes were cited as involved. In seventy-one instances the extent of lung involvement was not adequately defined in the histories or protocols.

Obviously the adequate use of oxygen by the newer methods of administration should afford strikingly valuable evidence as to the importance of anoxemia in the determination of death in pneumonia. Naturally, at the present time, a very wide difference of opinion exists in regard to this method of therapeutics; the matter is still in active dispute. That oxygen tremendously increases comfort in many cases and that it often prolongs life, seem to be facts beyond dispute, but in my observation it has little if any permanent effect in septic cases or in those in which grave circulatory defects have developed. I do not feel that it manifestly modifies prognosis materially, in cases showing grave

pathologic changes, such for example as in massive collapse, atelectasis or embolism.

Of the cases in which pulmonary changes seemed to play the important rôle in the cause of death, I must cite twenty cases of empyema, in which lung compression had been considerable, but in all of which a basic septicemia was present; atelectasis due to plugging of a bronchus with tenacious exudate was present in nine instances, and massive collapse in four. In none of these last mentioned lesions had the precise nature of the pathologic condition been recognized clinically, and subsequent observation has convinced me that these lesions are much more frequent and very much more important than I, at least, have previously recognized. In the four instances of massive collapse this lesion was in all probability the immediate cause of death, and in at least some of the nine cases of atelectasis it too had been an important immediate lethal factor. Pulmonary embolism, which I previously esteemed to be a not infrequent immediate cause of death in pneumonia, occurred but once and the lesion in this case was very small and probably relatively unimportant. I suspect that massive collapse and atelectasis from various causes have generally been mistaken for pulmonary embolism. Emboli other than in the lung occurred in but two instances, in neither of which did it seriously contribute to the fatal outcome. Pulmonary gangrene was a prominent lethal factor in two instances.

Most textbooks stress the importance of tuberculosis in connection with death in pneumonia. Chronic healed pulmonary tuberculous lesions were found in but eighteen cases of the series. In none of these did they play a rôle in the cause of death. In two cases, however, there had developed an activation of an old lymphatic tuberculosis with generalized tuberculosis and death as a result. It is very probable that most physicians have overestimated the rôle of tuberculosis as a fatal factor in the termination of pneumonia.

Many physicians, including myself, have much emphasized the rôle which alcoholism plays in the fatalities from pneumonia. In this series but five instances of this nature appeared. It is then quite possible that we have been overestimating this factor in pneumonia fatalities, but I cannot refrain from stating that I nonetheless feel that chronic alcoholism, with its attendant exposure and other concurrent factors, at least looms large as an important factor in susceptibility to the disease. Ten instances of this probable relationship, including the five cases already cited, seem to bear out this assumption.

Wonder has often been expressed because so few cases of pneumonia terminate from serious renal defects, for renal irritation and congestion are usually a prominent sign at onset. Only three instances in which active nephritis was present were observed in this series. In none of them had it assumed clinical importance, nor was it cited as a contributory factor in the cause of death.

Very numerous other and exceedingly interesting facts have discovered themselves in this brief study. The limitation of this paper, however, permits discussion of only the most important and striking observations. Grounds for many studies both in the clinic and in the deadhouse have, however, been suggested, and though the subject may seem to some to be threadbare and reduced to mere osteology by the overwhelming literature concerning the bacteriology and serology of pneumonia that has appeared in recent years, it is

apparent to the student of clinical medicine that much time may still be profitably spent in the study of the clinical features and pathology of pneumonia.

CONCLUSIONS

I feel that the facts cited justify the following conclusions:

The most serious basic factor in the cause of death in pneumonia is sepsis.

Patients with pneumonia most frequently die immediately from circulatory failure. In this term must be included both essential cardiac failure and peripheral vasomotor paralysis.

Anoxemia is not a frequent immediate cause of death in pneumonia.

Atelectasis and massive collapse are probably more frequent as terminal factors than is generally supposed.

Embolism and thrombosis are probably rare as terminal causes in pneumonia.

47 West Ninth Street.

ABSTRACT OF DISCUSSION

DR. J. H. MEANS, Boston: Some eighteen years ago I had the privilege of working with Dr. L. H. Newburgh on this problem. That work, I think, is largely out of date, but I will mention it briefly. Dr. Newburgh tried, both in the clinic and experimentally, to answer this very question Dr. Brooks has been attacking. Do the patients die of a vasomotor collapse or is the vasomotor center exhausted? The methods used seemed to give a negative answer to that; the vasomotor center carried on effectively. An attempt was made to answer in experiment whether death is due primarily to myocardial failure. The study was carried out in dogs, the Friedländer bacillus being used. I have to admit that it is quite remote from human pneumococcal pneumonia. These experiments seemed to show that the heart muscle carried on fairly well and that the blood was poisonous to it. Then the respiratory center was studied in dogs with Friedländer pneumonia, and some evidence seemed to indicate failure. This again was far removed from human lobar pneumonia. Since then other things have come up for consideration. At one time I thought that acidosis played an important rôle in pneumonia—carbon dioxide acidosis. I doubt this now. I don't believe it plays any rôle at all. I don't believe that the rôle of anoxemia in death from pneumonia is known. I do think oxygen therapy should be used. If I had pneumonia and was cyanotic, I should want oxygen given. It is impossible to determine with any degree of statistical accuracy whether a given method of treatment reduces mortality or not. I use oxygen therapy for any patient with pneumonia who is unduly cyanotic or shows undue respiratory stress. Likewise, when the circulatory symptoms loom big, oxygen therapy should be used and used reasonably early before the patient is actually moribund. These patients have a chloride deficiency, and my colleagues Dr. A. V. Bock and John Talbott have some evidence to show that it is desirable to give the patient with pneumonia a large salt intake to offset the chloride loss, because deprivation of chlorides leads to untoward symptoms. Intoxication, sepsis and infection play an important rôle.

DR. L. J. MOORMAN, Oklahoma City: Present knowledge of the ultimate phenomena of life and death is inadequate. No doubt every thoughtful clinician will acquiesce in the belief of Dr. Brooks that, in the great majority of cases, the ultimate cause of death in pneumonia is circulatory failure. Those who have entertained this belief welcome the corroborative evidence revealed by his investigations. However, for the benefit of those who may be content with the present understanding of the cause of death in pneumonia, attention is called to certain principles expressed by Aretaeus seventeen centuries ago. In the translation by Francis Adams is the following introduction to the chapter on pneumonia: "Animals live by two principal things—food and breath. Of these by far the more important is respiration. In the midst of the lungs is seated a hot organ, the heart, which is the organ of

life and respiration. If, therefore, the heart suffers primarily, death is not far off." With a liberal interpretation of this statement, it must be admitted that Arctaeus, seventeen hundred years ago, was observing and recording the same phenomenon observed and recorded by Dr. Brooks. It has been said that life has but two legs on which to stand, the heart and the lungs. Bichat taught that death may have its origin in the heart, in the lungs or in the head. Since the nerve centers hold the secret of life and death, Bichat's teachings must be accepted. However, it should not be forgotten that the vital centers cease to function the moment circulation becomes inadequate. Though death may seem to be due to respiratory failure or to interrupted function of the vital centers, in the last analysis it is, in all probability, circulatory in origin. Limited knowledge with reference to the cause of death constitutes a serious indictment of the medical profession and suggests a fascinating field for future investigation. May I suggest that well organized hospitals consider the advisability of team work in the study of the cause of death; the coordinated efforts of the experienced clinician, the skilled physiologist, the biochemist and the pathologist should ultimately lead to definite advances in knowledge regarding this difficult problem.

DR. MAXWELL FINLAND, Boston: Dr. Brooks has rightly emphasized the importance of bacteremia and the consequent focal infections as the most serious factor in the cause of death from pneumonia. Bacteremia may be considered a manifestation of the failure of the immunologic defense. Our experience with serum treatment at the Boston City Hospital has led us to feel that the administration of type-specific antibody helps to overcome this difficulty. This is evidenced by the rapid and permanent clearing of the bacteremia or by preventing its appearance, and also by the prevention of the spread of the pulmonary lesion. To attain such an effect the antibody must be type specific for the invading organism, and it must be given in adequate amounts and early enough in the disease. When the infection has progressed to a stage at which the fixed and circulating phagocytes have been sufficiently injured, or when purulent foci have become established, we feel that such antibody is of little avail. In considering circulatory failure, which Dr. Brooks has noted as the important immediate cause of death, one must take into account the degenerative changes related to age. The well established fact that the death rate from pneumonia increases steadily with advancing age depends largely on this factor. Among our type I patients, 56 per cent were under 40 years of age and only 23 per cent were over 50. In spite of this well known predominance of type I pneumonia in the younger age groups, only 28 per cent of patients with this type coming to autopsy were under 40, and 58 per cent were over 50. Among the latter, chronic cardiovascular lesions, either gross or microscopic, were the rule. Among nineteen patients under 50 years of age, however, the only cardiac abnormalities noted were two instances of right-sided dilatation, one case showing acute vegetations grafted on a healed rheumatic endocarditis, and one case of fibrinous pericarditis. Our incidence of endocarditis is considerably lower than occurred in the series of Dr. Brooks. I am interested in the frequency of so-called acute cardiac lesions in the cases of Dr. Brooks. It is not clear to me what conditions are included among such lesions. In the cases of pneumococcal pneumonia which Dr. Sutliff and I studied, instances of acute necrosis of the myocardium, either infectious or toxic, were not encountered. Dr. Parker, director of the Mallory Institute of Pathology, who examines microscopically the sections from our cases, believes that such changes are extremely rare in pneumococcal pneumonia. He has encountered such necrosis, however, in cases of hemolytic streptococcus sepsis. Since most of the cases in the army were in young adults, I should like to ask Dr. Brooks whether the high incidence of cardiac dilatation noted in the camps might not have been related to the frequency of hemolytic streptococcus invasions complicating the pneumonias at that time, particularly those related to epidemics of influenza and measles. We have not encountered any instance of meningismus in which lumbar puncture revealed normal spinal fluid and in which evidence of an inflammatory lesion of the brain or meninges was discovered at autopsy. I should like to ask

whether Dr. Brooks' opinion in regard to meningismus is based on such observations.

DR. ROBERT G. TORREY, Philadelphia: Dr. Brooks called attention to the importance of circulatory function in pneumonias and minimized the toxic effect of pneumococcal infections. There is no chance for denial of the importance of the toxic factor with profound and prolonged sepsis, but most of our cases do not show that picture. Most of these patients die of circulatory failure. Dr. Brooks dwelt less on the failure of the pulmonary than of the peripheral circulation, but I believe observation will indicate that the sudden change evident in the patient with the onset of pneumonia and the stress is due to failure in the pulmonary circulation. It is a sudden failure which causes the distress characteristic of pneumonia, and its prolongation causes a vascular strain, which is reflected in peripheral failure. All physicians are interested in the treatment of pneumonia, and that consists in combating these complications. Pulmonary congestion, with its respiratory difficulties, and pulmonary edema, or wet lung, have to be met by heroic measures. It seems reasonable not to wait to meet this circulatory strain when it occurs but to forestall it if possible. In the past two years I have treated patients at the Philadelphia General Hospital and at the Woman's College Hospital with measures aimed at this end as a routine, and I have been more than satisfied with the apparent results. That is, in cases showing respiratory distress seen early, very drastic dehydration is attempted by eliminating fluid intake to 24 ounces in twenty-four hours, limited to orange juice or milk with no added water, and no other food. The patients complain much less than would be imagined, and the relief seems to be gratifying. We combat coughing and distress with sedatives, preferably powder of ipecac and opium, in small doses at frequent intervals in the beginning. This probably also encourages sweating, thus aiding dehydration. It seems more reasonable to reduce the work of the heart and the circulation early than to try to combat the failure after serious damage has been done. Simple and very drastic and severe dehydration seems to have a reasonable effect in reducing what used to be called toxemia but which is now believed in many cases to be pulmonary circulatory distress.

DR. A. L. BARACH, New York: One has to view lobar pneumonia not only as a disease characterized by pneumococcal toxemia or by terminal circulatory failure but also by a variable disturbance in the oxygen absorbing function of the lung. In a series of 285 cases at the Presbyterian Hospital in the past eight years I have observed twelve cases in which oxygen treatment was withdrawn before the disease process in the lungs had cleared. The resultant collapse was evidence of the sustaining effect of oxygen, as was also the fact that most of them returned to their former state when oxygen was again provided. Before it was known that anoxemia was a factor in the mortality of pneumonia, two patients were taken out of an oxygen room prematurely. The circulatory and respiratory failures were so severe as ultimately to cause death. The second function of the lungs, the elimination of carbon dioxide, presents no difficulty to the pneumonia patient. However, in those cases in which marked pulmonary involvement is present, the inhalation of 50 per cent oxygen frequently sustains life until the patient is able to develop immunologic resistance to his disease. When circulatory failure is spoken of, one ought to bear in mind that oxygen want is itself a noted cause of circulatory failure. Myocarditis has been produced by exposure to a lowered content of oxygen in the inspired air in animals. The degree of arterial anoxia required to accomplish this may not infrequently occur in the pneumonia patient. Granted that sepsis is a frequent cause of death, one must also grant, as Dr. Finland pointed out, that the death of many pneumonia patients is associated with the maximal lung involvement. I think it is fair to state, therefore, that one must bear in mind the function of the damaged lung in the treatment of pneumonia as well as the toxemia caused by the pneumococcus organism.

DR. HARLOW BROOKS, New York: I worked at this subject during the war and have been working at it ever since. Every alternate patient who has come to my service during these years has received some specific method of treatment.

I wish I were as enthusiastic about the use of serum as I was ten years ago. We have a corps of workers especially trained to conduct this work with my full cooperation. Their faith is beginning to waiver as they see more cases. So I have said nothing about specific serum. My object is to find out how they died; then perhaps I may find out why they died, and then some other generation may find out how to keep them from dying. That I feel no one is prepared to speak on with much authority as yet. The war streptococcus cases are probably not similar to those on which these data of today are based. It was the type of the exudate and the embarrassment of the pulmonary circulation, which Dr. Torrey mentioned, which would probably distinguish this type of pneumonia, the A. E. F. type, from that with which we are dealing at present. The question of peripheral circulatory failure is an exceedingly interesting problem. We have been working on the chemical and bacteriologic sides of this subject also but I, dating back to my original training, have taken the pathologic side of the question. Until we know how they die, I do not think we shall be able to change the mortality rate.

NEUROLOGIC MANIFESTATIONS OF HYPERINSULINISM AND OTHER HYPOGLYCEMIC STATES

EDWARD H. RYNEARSON, M.D.

AND

FREDERICK P. MOERSCH, M.D.

ROCHESTER, MINN.

The neurologist so frequently is confronted with diagnostic problems involving bizarre nervous symptoms that he should acquaint himself with syndromes which may have as a predominating symptom some nervous manifestation, although the underlying disease may be outside his special field. Hyperinsulinism and hypoglycemia are conditions of this type, and, although not primarily of neurologic importance, the presenting symptoms may be of a distinctly nervous character.

Symptoms from both overactivity and underactivity of the endocrine glands generally have been recognized. Thus both exophthalmic goiter and myxedema have been attributed to the thyroid gland for many years. For some unknown reason, however, the recognition of symptoms resulting from the overactivity of certain glands has lagged behind the recognition of the symptoms of underactivity. Diabetes, parathyroid tetany and hypoadrenalism (Addison's disease) were described long before hyperinsulinism, hyperparathyroidism and hypersuprarenalism.

We are limiting this paper to conditions that are the antithesis of diabetes, in which symptoms are produced by an insufficiency of sugar in contrast to an excess. Further, we are going to focus our attention more on symptoms than on pathologic conditions or on treatment, and special attention is to be called to the preponderance of neurologic symptoms in these conditions. No effort is made to review in detail the rapidly accumulating literature on the subject; such a review may be obtained from any thorough article.¹

From the Division of Medicine and the Section on Neurology, the Mayo Clinic.

Read before the Section on Nervous and Mental Diseases at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

Narcolepsy Associated with Hyperinsulinism; of Epilepsy and of One Case of Narcolepsy Cured Clinically by Partial Resection of Body and Tail of Pancreas, *J. A. M. A.* 100: 321-328 (Feb. 4) 1933. Sigwald, Jean: Les hypoglycémies spontanées, *Paris méd.* 85: 321-332 (Oct. 22) 1932. Wauchope, G. M.: Hypoglycemia: Critical Review, *Quart. J. Med.* 2: 117-156 (Jan.) 1933. Wilder, R. M.: Hyperinsulinism, *Internat. Clin.* 2: 1-18 (June) 1933.

Many efforts have been made to classify the possible causes of hypoglycemia, and a very good classification is the one given by Wauchope,¹ as follows:

1. Excess of insulin. This may be the result of therapeutic injections of insulin, of tumors and hyperplasia of the pancreas, or of functional hyperinsulinism (idiopathic hypoglycemia).

2. Lack of opposing secretions. This condition may result from disease of the suprarenal glands, from tumors of the anterior or posterior lobe of the pituitary body, or from myxedema.

3. Lack of glycogen. This lack may result from destruction of reservoirs, from disease of the liver or wasting of muscles, from abnormal secretion of sugar, from renal diabetes, from lactation, from active depletion of stores, such as occurs in muscular exercise, and from failure to replenish stores as in starvation.

4. Interference with regulating center. This may result from another nervous disease which affects the pons, or from overaction of the vagus nerves.

These causes usually are complex, and they must be so because the mechanism involved in the metabolism of carbohydrate is so complicated. Many factors are involved in the metabolism of carbohydrates; among others, the amount of carbohydrate ingested and the amount absorbed, the production of glycogen and its deposition in liver, muscles and other tissues, and glycogenolysis and utilization of dextrose. Any condition that interferes with any of these steps will itself produce symptoms which further add complexity to an attempted classification of the causes of hypoglycemia. Thus many investigators who have attempted to classify these etiologic factors have as one heading "endocrine disturbances," beneath which is listed practically every endocrine gland in the body. Perhaps this is justified; perhaps every endocrine gland does affect carbohydrate metabolism. However, it is difficult to see how this clarifies the situation. Diagnosis is the most important part of the problem of hypoglycemia. Once the diagnosis has been made, the various steps in carbohydrate metabolism can then be reviewed and an attempt made to locate the precise etiologic factor responsible. Just how difficult this is can be appreciated only by one who has tried to do it.

Strangely enough, the symptoms of hypoglycemia have been known only since the discovery of insulin in 1921.² It was not until 1924 that Harris³ called attention to the possibility that hypoglycemia might develop among certain patients from an oversupply of the patient's own insulin, and it was not until 1927 that such a case was reported;⁴ namely, that of a physician who suffered and finally died from spontaneous hypoglycemia due to carcinoma of the island cells of the pancreas. Since then, numerous other cases of hypoglycemia from tumors of the island cells have been reported, and many patients have been cured by surgical removal of the adenoma. Another group of cases of hypoglycemia has been reported in which the condition resulted from primary disease of the liver.⁵

The pituitary gland is suspected of being of etiologic importance in other cases of hypoglycemia, and, while there is experimental evidence to bear out this relationship, there have been no proved clinical cases, although Josef Wilder⁶ suggested this diagnosis in two cases.

Cases that are clear-cut examples of uncomplicated hypoglycemia are those in which symptoms definitely are the result of hypoglycemia and in which removal of a tumor of the island cells of the pancreas causes disappearance of all symptoms. The patients in such cases may be said to suffer from hyperinsulinism, a term often loosely applied to a variety of vague symptoms among patients whose pancreas never is examined. They complain of the same symptoms as does the diabetic patient who has received an excessive amount of insulin, and every physician is familiar with such symptoms. These patients are perfectly normal after the ingestion of carbohydrate food. Such a history, together with a low reading for blood sugar, is all that is necessary for the diagnosis of spontaneous hypoglycemia. The advisability of surgical exploration to establish the presence or absence of adenoma of the island cells of the pancreas will be considered later.

There is no doubt that hundreds of persons are suffering from undiagnosed spontaneous hypoglycemia. This paper is being presented for the consideration of neurologists and psychiatrists because we believe that they have the best opportunity of making this diagnosis, since by the very nature of the symptoms these patients present what appears to be a neurologic problem; this was pointed out by Harris,¹ by Wolf and his associates⁷ and by others.

In preparation for this paper we reviewed all cases of spontaneous hypoglycemia that had been reported, to see how many patients presented neurologic symptoms. The answer was quickly obtained: they all had neurologic symptoms of one type or another. The striking feature was the fewness of symptoms that were not neurologic,⁸ evident in Tedstrom's report, as follows: Weakness or prostration occurred in thirty-seven cases, and its allied condition of fatigue in ten cases; that is, forty-seven cases, the two symptoms taken together. Stupor occurred in seven cases and coma in thirty-nine; that is, forty-six cases, the two symptoms taken together. Muscular twitching occurred in eight cases and convulsions in twenty-six cases; that is, thirty-four cases, the two symptoms taken together. Loss of memory occurred in twenty cases, sweating in nineteen and change in general behavior in eighteen. Disturbance of speech was encountered in eighteen cases, as follows: Speech was unintelligible in eight cases; motor aphasia was present in five cases, and the speech was slow in three cases, monotonous in one case and slurring in one case. Nervousness was a characteristic in fifteen cases. Restlessness occurred in eight cases, and its allied condition, mania, in seven cases; that is, fifteen cases, the two symptoms taken together. Fourteen patients were mentally confused, and the same number had epileptiform seizures. In twelve cases hunger was excessive. Ocular symptoms were present in twelve cases, as follows: diplopia in five cases, dim-

ness of vision in three cases, dilated pupils in two cases, blurred vision in one case and unequal and miotic pupils in one case. Ten patients were troubled with vertigo, and an equal number with dulness and listlessness. Nausea was present in three cases and vomiting in seven; that is, ten cases, the two symptoms taken together. Headache was present in nine cases and drowsiness in nine. Each of the following symptoms was found in a respective group of eight cases: fainting, tremors, epigastric pain and a positive Babinski sign. Vague paresthesia was encountered in six cases. Loss of sphincteric control, irritability and emotional instability were characteristic, each in a respective group of five cases. Four patients foamed at the mouth, and four were pallid. Three patients had fear of death.

Attacks of unconsciousness and even convulsive seizures often are prominent symptoms and, not uncommonly, a diagnosis of epilepsy is made in these cases. This naturally calls attention to the need for considering hypoglycemia as a possible etiologic factor in every case in which the patient presents himself with a history of having had convulsions. Because of the behavior disturbance and other associated symptoms a diagnosis of acute alcoholism occasionally is made. One of our patients carried a slip of paper on which was written "I am not drunk, I am sick. Make me drink orange juice if you can; if you can't, call Dr. ———." We have seen cases in which a diagnosis of tumor of the brain, and even of insanity, had been made when patients were suffering from hypoglycemia, and in which, following administration of carbohydrates, the patient made a miraculous although temporary recovery. Attention also is called to the frequent presence of a positive Babinski sign, which disappears when the blood sugar is raised to normal levels. It should be mentioned that the severity of symptoms varies with different individuals and with different levels of blood sugar. Some patients have severe symptoms when the concentration of sugar is 60 mg. per hundred cubic centimeters of blood; others have few symptoms when the blood sugar is 40 mg. One of us (Ryneerson) during the course of an experiment was found to give a reading for sugar of 30 mg. per hundred cubic centimeters without appreciable symptoms.

It is an interesting commentary that, frequently, in cases in which spontaneous hypoglycemic attacks occurred, the patient or some member of his family had discovered that a relationship existed between the attacks and the ingestion of food. The following case exemplifies this:

CASE 1.—A laborer, aged 45, had enjoyed good health until four years prior to his admission to the clinic. At that time he had begun to have symptoms resembling those of drunkenness. These had occurred between meals, had been much more likely to occur if he had worked hard, and had been relieved by taking food. On one occasion he had had a characteristic epileptiform seizure, followed by unconsciousness, which had lasted sixteen hours. When he awoke, he had been mentally confused until he had drunk some milk, when he rapidly had become normal. About this time he and his friends had realized the value of food in relieving these symptoms, so that on another occasion, when he had been unconscious for twenty-six hours, a friend had revived him by forcing him to drink milk. He had complained of a severe headache, in conjunction with these symptoms, which had persisted in varying forms during the entire four years.

The clinical diagnosis of spontaneous hypoglycemia was confirmed by a reading for blood sugar of 30 mg. per hundred cubic centimeters. At operation, a tumor of the island cells of

6. Wilder, Josef: Ein neues hypophysäres Krankheitsbild: Die hypophysäre Spontanhypoglykämie, *Deutsche Ztschr. f. Nervenhe.* **112**: 192-250 (March) 1930.

8. Tedstrom, M. K.: Hypoglycemia and Hyperinsulinism, *Ann. Int. Med.* **7**: 1013-1025 (Feb.) 1934.

the pancreas was discovered, which was diagnosed carcinoma. Immediately following the operation the level of sugar in the blood returned to normal and hypoglycemia never occurred again. The patient has been in excellent health since the operation and has not had symptoms of any sort.

In this history there are several important features: the patient's symptoms were present only when he was hungry, they often were produced by exercise, they were essentially of neurologic character, they were relieved by the ingestion of carbohydrate, and they disappeared entirely following surgical removal of an adenoma of the island cells of the pancreas.

Medical treatment of hyperinsulinism has uniformly been unsuccessful. It is true that certain patients with symptoms of hypoglycemia of unknown etiology may obtain relief from such medical measures as frequent feedings, but in these cases a diagnosis of hyperinsulinism should not be made; a diagnosis of hyperinsulinism should be reserved for cases proved at operation or at necropsy.

Regarding the character of the tumor, Bensley⁹ recently has written: "I wish very much that I could say something which would stop the clinical people from calling these tumors associated with hypoglycemia 'beta cell tumors.' The one thing that is conspicuous in all that I have examined so far is that they are actually neoplastic cells with some resemblances to island cells, probably producing insulin or some related substance." Certainly this opinion has strong clinical support. It is discouraging to operate on a patient who has had hyperinsulinism for years and find that, because of delay in diagnosis or in surgical intervention, the adenoma has become inoperable as a result of extensive metastasis. So many carcinomas give no warning signs of their presence; yet here is one type that shrieks for attention. It would seem advisable to subject all patients with this syndrome to abdominal exploration, since there is no method at present of diagnosing a tumor preoperatively. The exploration itself is attended with little risk; no deaths have been reported as a result of it. If a tumor of the island cells of the pancreas is not found, treatment must, in view of present inadequate knowledge, remain palliative.

The mechanism involved in the production, by hypoglycemia, of neurologic and psychic symptoms is not definitely known. Olmsted and Logan¹⁰ expressed the belief that insulin convulsions are caused by the action of insulin on the bulbar centers. They found that decapitated cats do not have convulsions, despite a low concentration of sugar in the blood, whereas convulsions are marked in decerebrate cats. They also presented evidence to support the hypothesis of the antagonism of solution of pituitary to insulin. Rudy¹¹ expressed the opinion that convulsions are the result of hypoglycemia itself, whereas Drabkin and Ravdin¹² felt that convulsions are related to water balance, since they had observed that water-starved dogs did not have convulsions despite pronounced hypoglycemia. Although the exact mechanism of the production of hypoglycemia is still unknown, it is definitely established that all tissues require sugar for normal function.

Patients suffering from convulsions or from temporary psychic disturbances should be investigated as to the possible presence of spontaneous hypoglycemia. Studies of the blood sugar in clear-cut cases of epilepsy have indicated relatively normal levels,¹³ although immediately following a seizure the amount of sugar in the blood may be low, owing to the tremendous exertion.

Among patients suffering from personality disorders, Henry and Mangam¹⁴ found relatively normal sugar tolerance curves. The presence of marked hypoglycemia, therefore, should be very suggestive, and further investigation should be carried out to determine its importance as an etiologic factor in the production of such neurologic or psychic symptoms.

SUMMARY AND CONCLUSIONS

This paper is presented to emphasize the universal occurrence of neurologic and psychic symptoms in severe hypoglycemia. It is hoped that through the cooperation of neurologists and psychiatrists many hitherto undiagnosed cases of hypoglycemia may be discovered. In the light of present inadequate knowledge, medical treatment is unsatisfactory, and it is only by early surgical exploration in these cases of hypoglycemia that adenomas of the island cells of the pancreas may be found and successfully removed. It is to be hoped that the time is not far off when it will be possible accurately to separate the various types of hypoglycemia and to treat each type better.

ABSTRACT OF DISCUSSION

DR. I. S. WECHSLER, New York: The paper of Drs. Ryneerson and Moersch calls attention to a problem that is occasionally confusing. I don't think it is quite as common as one might get the impression, although I have seen at least half a dozen different reactions to hypoglycemia and hyperinsulinism. I am glad the authors make proper distinction between the two conditions, as it is important clinically and pathologically to distinguish between them. I have seen a case of hemiplegia in which all the signs disappeared promptly with the administration of dextrose. This patient had received an excessive dose of insulin. The occurrence of a Babinski sign in hyperinsulinism without hemiplegia is rather well known. I saw a patient who had convulsions and died of adenoma of the pancreas. The patient used to slump, have convulsions, thrash about, become unconscious for a long time, and spontaneously come out of the stupor. I have also seen one case of epilepsy following hypoglycemia. Recently I have seen patients with all sorts of psychiatric manifestations, abnormal involuntary movements such as chorea and dystonia, and bizarre hysteroid manifestations. There is no doubt that many so-called psychoneurotic symptoms occur in the course of hyperinsulinism and hypoglycemia. It is well therefore to make blood sugar determinations in all obscure cases and treat them if necessary. As to subjecting every patient to an operation, that is not so simple. I will take the authors' word for it that the operation is not serious. To me it would rather seem a heroic thing to do; but there may be isolated instances in which one could justifiably do an exploratory laparotomy.

DR. GEORGE W. HALL, Chicago: I have not had much experience with convulsions in these cases. However, I have seen a few cases in which definite neurologic symptoms have appeared. It is interesting to note how few marathon racers have had difficulty after the race. One important point that

the authors brought out is that hyperinsulinism may be mistaken for drunkenness. The patient may become neglectful of his work and stagger about as though he were drunk. He feels weak before eating his breakfast and staggers around a great deal. After breakfast he goes along fairly well until lunch time, when he notices that he is weak again. One may be inclined to think he is drinking, but as has been reported in some cases it has been found that the patient does not use liquor in any form. Tests of the blood sugar show that it is much below normal. The symptoms in these cases are necessarily individual. Some will respond in a very different way from others, as the authors have noted.

DR. HARLOW BROOKS, New York: I see a good many minor manifestations of these symptoms among women who are dieting to reduce weight and who cut down their sugar, starch and carbohydrate intake in general. The first case that I saw was one in which a young woman had chosen to reduce her weight and at the same time carry on an active athletic life. The result was a blood sugar of 10, which appeared every morning at 2 o'clock. These conditions are quite frequent, and I am sure that the authors would feel as I do that it would not be wise to do an exploratory laparotomy until the diet had been carefully considered. The low sugar diet, in association with exercise, will frequently cause the whole picture described by the authors. The first case that I saw was under the care of a famous psychiatrist and had been diagnosed as a case of hysteria. It was a case of starvation diet.

DR. TOM B. THROCKMORTON, Des Moines, Iowa: My contact with this rather new entity was thrust on me unexpectedly last summer when a young woman was referred to me from the northern part of the state, suffering from narcolepsy. In association with the narcolepsy a psychasthenic condition had developed in which fear played the predominant rôle. The maternal instinct of the patient was such that she had a great fear something would happen to her baby during one of these attacks of involuntary sleepiness. The general physical and neurologic examination failed to reveal anything, and I so wrote the referring physician. Fortunately, a coincidence happened. In the mail of that day came reprints from Dr. Seale Harris on this subject of narcolepsy associated with hyperinsulinism and the hypoglycemic state. After reading them I immediately wrote the physician that perhaps it might be well if a chemical examination of the blood be made, particularly in regard to the lowering of the sugar content. This was done and he wrote me that a very low blood sugar was found. Following my suggestion that the patient be placed on a high carbohydrate intake, he later stated that she had practically been relieved of her attacks of narcolepsy and that the psychasthenic state of fear had been largely removed.

DR. EDWARD H. RYNEARSON, Rochester, Minn.: Reference has been made to the occurrence of low values for sugar in the blood of marathon runners. In a study of those who finished the 26 mile marathon race in Boston, it was found that there was great variation in the values for blood sugar, depending to a great extent on the runner's physical condition; those who lost usually had low values for blood sugar. Unquestionably, the blood sugar was affected by the amount of carbohydrate consumed during the race. Dr. Brooks referred to a patient whose symptoms improved following her return to a normal dietary regimen. Certainly, in such a case operation should not be performed. However, this case illustrates a point that we have tried to make; namely, the importance of distinguishing the mild and usually vague symptoms of hypoglycemia from the severe symptoms resulting from the marked lowering of the blood sugar resulting from possible hyperinsulinism. We do not advise surgical exploration of the abdomen of a nervous girl the fasting value of whose blood sugar is 60 mg. per hundred cubic centimeters, but we do advise an exploratory operation for a patient the fasting value of whose blood sugar is 20 mg. per hundred cubic centimeters and who is likely to become unconscious if he does not partake largely of foods high in carbohydrate every three hours, both day and night. This has been referred to as a rare condition. Although, unquestionably, it is not of frequent occurrence, I am of the opinion that the condition in many cases is not diagnosed.

THE KRUKENBERG TUMOR

REPORT OF A CASE WITH RECTAL INVOLVEMENT,
PRODUCING STRICTURE

F. G. RUNYEON, M.D.
READING, PA.

In 1896 Friedrich Krukenberg described a tumor of the ovary which he called fibrosarcoma mucocellulare carcinomatodes. He considered this tumor to be a fibrosarcoma containing large epithelioid cells enclosing mucin, which induced him to add the name mucocellulare carcinomatodes.

Krukenberg maintained that the tumor was primary in the ovary, a view that has been much discussed and opposed. At the present time most observers consider it to be secondary to carcinoma in some portion of the gastro-intestinal tract.

In 1918 Major¹ in a classic paper collected fifty-five cases from the literature and discussed in a complete manner the opinions expressed by various authors as to the conflicting views concerning its origin, mode of transmission and pathologic appearance.

In 1929 Fallas² collected twenty-three more cases, and Enzer³ collected six cases and reported one in 1930.

TABLE 1.—Record of Cases Studied

Reference	Contribution	Cases	Year
Major ¹	Collected	55	1918
Pribram, E. E.: Arch. f. Gynäk. 116:343	Reported	1	1921
1921	Collected	23	1923

Enzer ³	Reported	1	1930
Tyner, J. D.: " " " " " "	Reported	1	1930
Babcock, W.	Reported	1	1930
10:271, 1930	Reported	2	1932
Stephens, H. W.: Ann. Surg. 96:1075, 1932	Reported	1	1934
Runyeon	Reported	1	1934
			Cases
Presenting only ovarian involvement			23
Presenting involvement of organs in addition to the ovary.			68
Total number of cases studied.....			91

These and the other cases reviewed in this article are shown in table 1. Of the twenty-three cases in which only ovarian involvement was reported, only two presented conclusive evidence by autopsy and microscopic study that other organs were not involved.

In the study of Krukenberg tumor there are two pathologic questions that attract attention: First, is this tumor primary in the ovary or is it secondary to some gastro-intestinal carcinoma? Second, how can one explain the combination of malignant connective tissue and epithelial areas?

Fallas² says that the primary growth is usually in the stomach but sometimes in the small intestine, the gall-bladder and the breast. He says that it is considered primary carcinoma and not sarcoma.

From the Proctologic Department of the Reading Hospital.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

I am indebted to Dr. Frederick Light and Dr. Erwin D. Funk of the Pathological Department of the Reading Hospital for their cooperation in the postmortem reports and the preparation of slides, to Dr. J. C. Bloodgood of Baltimore and Dr. J. I. Fanz of Philadelphia for verification of the pathologic diagnoses and to Dr. Horace Long for his help in the collection of data and reports of previously collected cases.

Wagner⁴ decides that "the picture of so-called Krukenberg ovarian tumor is due to the mucoid degeneration of epithelial cells in a scirrhous carcinoma of the ovary (whether primary or secondary to a carcinoma of the stomach)."

Matters⁵ says that Erdheim and Schiller have shown the Krukenberg tumor to be a pure carcinoma and always secondary to carcinoma of the gastro-intestinal tract or of the gallbladder. The cancer cells from these parts are said to fall on the ovary and to become implanted there but, being secreting cells, they continue to produce secretion and become distended, as there is no gland lumen into which to pour their secretion. The cells invade the ovary in small groups or in a diffuse manner. The cell, distended by its own secretion, pushes the nucleus to one side, flattening it against the side wall and producing the well known signet ring described by Krukenberg. The presence of these distended cells markedly irritates the connective tissue of the ovary and so stimulates it as to produce the appearance of a fibrosarcoma.

In the discussion of Miller's⁶ report of a case, J. F. Browne of Edinburgh suggested "the possibility of three types of tumors producing the microscopic appear-

theory that it is usually secondary to a carcinoma of the gastro-intestinal tract."

Miner⁸ reported a case that looked like one of primary unilateral Krukenberg tumor one year after operation in a woman, aged 19. The report that was made, Nov. 23, 1933, shows that this woman is alive and well and has become the mother of three healthy children since the operation. Dr. Miner submitted the slides obtained from this case to a number of pathologists for opinions. Some diagnosed it a Krukenberg tumor, some claimed it to be a follicular carcinoma and some a sarcoma. It is likely that it was not a Krukenberg tumor.

Greenhill⁹ reported an operation on a patient in October 1930 in which all tests to determine a primary lesion in the gastro-intestinal tract have been fruitless. The patient died two months after operation without autopsy.

Why is it necessary that the ovarian picture must always be a secondary one? Cannot a carcinoma of the same type originate in the ovary primarily in some certain cases and by its presence stimulate the connective tissue cells of the ovary to the same growth that is produced by a carcinoma originating in the stomach and secondarily involving the ovary?

This surely can be possible and would readily explain the cases in which no carcinoma has been found in other abdominal organs. True, gastro-intestinal carcinoma has been found in most of the cases that have come to autopsy, but there are a few remaining in which there is reasonable certainty that only the ovary was involved. Wagner⁴ concurs in this view.

It is very evident from table 2 that, in the cases reported in which the data have been sufficiently accurate and definite to determine the location of lesions, most of the cases have presented an involvement of the gastro-intestinal tract. Some cases showed lesions in a number of organs.

Many of the recorded cases did not come to autopsy and therefore did not reveal a list of the organs involved. The sixty-eight cases (table 2) selected out of the ninety-one studied did give records sufficiently complete to plan the diagram. These observations make this tumor as important to the gastro-enterologist as to the gynecologist.

The case that I report invites the attention of the proctologist to this tumor, making it a differential diagnostic problem in strictures of the rectum.

REPORT OF CASE

Mrs. H. S., aged 64, white, had had attacks of pain in the epigastrium and right hypochondrium for several years, associated with nausea, vomiting, anorexia and weakness. At the examination, April 22, 1931, the examiner noted a sensation of a mass in the epigastrium which was firm and somewhat tender. He diagnosed carcinoma of the stomach or gallbladder disease.

Four months later, in August, at which time she first came under my observation, she had frequent attacks of diarrhea with some incontinence. At times she could control the sphincter and at others she had no control.

She was admitted to the hospital and a marked constriction of the rectum was found, starting about 3 inches above the anus, through which the finger could not be passed. The wall was fairly smooth and superficially ulcerated with some small nodular swellings at the lower end of the stricture. One of the nodules was removed for examination; a report was made that there was inflammatory mucous membrane but no malignancy.

TABLE 2.—Organs Involved in the Sixty-Eight Cases That Show Lesions Other Than in the Ovary

Organs	Frequency of Involvement
Stomach	71 cases
Small intestine ..	5 cases
Appendix	2 cases
Sigmoid	4 cases
Rectum	2 cases
Remainder of colon	3 cases
Gallbladder	1 case
Liver	2 cases
Spleen	1 case
Omentum	2 cases
Uterus	4 cases
Ureter	1 case
Breast	2 cases
Lungs	1 case
Bone	1 case
Dura	1 case

ance found in Krukenberg tumor. In one they may be entirely sarcoma, the signet ring cells being derived either from spindle cells or from round cells. In the second possibility they could be entirely carcinomatous, the signet ring cells arising from mucinous degeneration of the cancer cells. In the third possibility both carcinoma and sarcoma may be present, the carcinoma being secondary to a tumor outside the pelvis. It has been shown that a carcinoma transplanted in rats can produce a sarcomatous change in the connective tissue of the host. One can conceive of no more favorable location for the stimulation of such a growth than in the ovary, where the stroma has such a peculiarly embryonic character and therefore might be supposed to be especially liable to such malignant properties."

Jarcho⁷ believes that he "has been able to follow the course of travel of cancer cells through the lymphatics to the ovary."

In March 1925 Miller⁶ stated that "no papers have yet been published that would dogmatically state the explanation of the peculiar structures of the Krukenberg tumor. The majority of cases would point to the

nant condition. A vaginal examination was not made. The blood Wassermann reaction was negative. Examination of the blood showed secondary anemia. The stricture was gently dilated and a blood transfusion was given, after which the patient improved in weight and strength and the diarrhea lessened. There were no gastric or pelvic symptoms during this period, no abdominal distention and no palpable mass in the epigastrium. The patient was discharged from the hospital in November. Rectal bougies were passed regularly to maintain a fair degree of comfort.

In July 1932 she came to the hospital again with more constriction of the rectum and an increasing anemia. Transfusions improved the blood picture and a Jelks operation for relief of the stricture was done, after which she had greater comfort, leaving the hospital again, August 29.

November 17, severe paroxysmal abdominal pains, distention and prostration suddenly developed. She was brought to the hospital and the abdomen was opened five hours after the pain started. There was some fluid in the abdomen; a rupture was found in the upper part of the sigmoid, the edge of the hole being necrotic. This rent was sutured. At this time numerous hardened whitish plaques were noted in various places on the small bowel, and in the ileum there was a markedly constricted area about 1 to 2 inches long with great dilatation above and below it, making it resemble an hour glass. The appendix

and submucosa was seen to be the result of the presence of large numbers of peculiar cells. These were large oval cells with an abundant acidophilic cytoplasm. The nucleus in some was oval and lay centrally. In others the nucleus was crescent shaped and was pressed against the rim of the cell. In these signet ring cells, the cytoplasm tended to be clearer and the cell margin became circular. Between these two extreme kinds of cells, all degrees of variation could be demonstrated. These tumor cells had no pattern of any sort but were scattered about at random, in the manner of an infiltration. A good many lymphocytes were also present. The tumor cells were limited

Fig. 1.—Krukenberg tumor, showing the ileum and colon involvement: K. T. shows successive points of constriction of the ileum due to tumor infiltration about 50 cm. above the cecum. D. I., dilated ileum, Co., colon; CE, cecum.

was seen to be involved in a definite hardening process. The walls were extremely thick and firm, making it look like a frankfurter. This induration extended slightly into the cecum. The appendix was removed for diagnostic purposes. Both ovaries were found enlarged but were not removed. There was a myoma on the uterus. The remainder of the abdomen was not explored, for obvious reasons.

The patient died on the sixth day after operation.

POSTMORTEM EXAMINATION

Postmortem examination, performed by Dr. Frederick Light of the Pathological Department of the Reading Hospital, showed in part the following:

Stomach.—The stomach was rather small and measured 21 by 7.5 cm. when opened. The pylorus was much thickened for a distance of 7 cm. and the wall in this area was 1.5 cm. in thickness. It was quite tough and cut with greatly increased resistance. In the fundus there were elevated patches in the mucosa which averaged 1 to 2 cm. in diameter. The remainder of the gastric wall varied from 0.5 to 1 cm. in thickness.

Section from the pylorus showed the usual thick circular layer of muscularis. The submucosa and the mucosa were greatly thickened. The mucosal glands, instead of lying closely side by side with only a little intervening stroma, were widely separated one from another, the tunica propria being much heavier than normal. The extensive thickening of the mucosa

Fig. 2.—Krukenberg tumor with bowel opened, showing points of constriction by the tumor, K. T., and of the dilated ileum, D. I.

almost entirely to the mucosa and submucosa, only a few being found in the muscularis. A few, however, could be found even in the outer muscular layer.

Ileum.—Approximately 50 cm. above the cecum was a tubular constriction of the ileum which extended for a distance of 16 cm. At this point the wall of the intestine was greatly thickened. It was above this point that the intestine was distended and bluish. Below this point the intestine was small, practically empty and grayish.

In the middle of the thickened segment the microscopic appearance was similar to that described in the stomach. The

Fig. 3.—Section of stomach under low power, showing the mucosa and a portion of the infiltrating tumor.

submucosa and mucosa were heavily infiltrated with tumor cells, most of which were of the signet ring variety. The glands were widely separated from one another by the thickened tunica propria. At the border of the thickened segment the mucosa retained its usual configuration, although there was some hemorrhage into the tunica propria, also; however, there was some infiltration of tumor cells into the subserosa.

Appendix.—The specimen weighed 6.5 Gm., measured 5 cm. in length, and averaged 1.2 cm. in diameter. The serosa

appeared smooth and glistening, with no gross evidence of a deposit of any exudate. The surface vessels were markedly injected over the entire surface, giving the specimen a fairly even red color externally. A fatty meso-appendix was attached throughout the entire length of the specimen. The organ was tough, firm and not at all pliable. When the specimen was sectioned, the cut surface bulged beyond the serosa. There was no differentiation between muscularis and mucosa on cross section, and the lumen was entirely obliterated to the most

very tough and measured 1.5 cm. in thickness, and its mucosa was edematous and rugosed.

Sections of the sigmoid were from near the site of the perforation. The microscopic picture was similar to that of the stomach. The submucosa and mucosa were densely infiltrated with lymphocytes and tumor cells and there was some invasion of the muscularis. Scattered typical colonic glands were found, with abundant goblet cells.

Uterus.—This measured 8 by 4.5 by 4 cm. and its wall was 2 cm. thick. There was a subserous fibroid at the fundus which measured 4.5 by 3.5 by 3.5 cm. It was well encapsulated and, on section, it was gray and showed whorls of tissue.

The small tumor mass in the uterus was composed of interlacing bundles of smooth muscle and fibrous tissue. No tumor cells such as those present in the stomach and ovaries were present here.

Ovaries.—The tubes were slightly thickened and adherent to the enlarged ovaries. The ovaries were replaced by tumor masses. There were two masses in the right ovary which were adherent to one another. The one measured 8 by 5 by 3 cm. and the other 6.5 by 3 by 2 cm. The smaller mass had a central cyst 1.2 cm. in diameter and contained clear fluid. The tumor mass in the left ovary measured 7.5 by 4 by 3 cm. All these masses were adherent to the pelvic wall, and all presented the same general appearance. All of them had a

Fig. 4.—Section of stomach under low power, showing the submucosa and a portion of the muscular layer infiltrated with tumor cells.

distal part of the organ. Just within the serosa was a ring of white tissue 2.5 cm. in thickness. This was distinguishable from a central core of yellowish tissue, which probably occupied the area of the former lumen. This central core measured 5.5 cm. in diameter.

This organ was removed at operation ante mortem and presented as a biopsy specimen. The subserosal tissues were edematous and bore a round cell infiltration. The muscularis was of normal thickness. The lumen and mucosal epithelium

Fig. 5.—Section of stomach under high power, showing the characteristic "signet ring" cells with compressed nuclei on the edge of the protoplasm.

were absent, a few small lymphoid follicles marking the site of the former lumen. The submucosa was tremendously thickened, accounting for about half the cross sectional area. Here again, in addition to the deposition of fibrous tissue, there was an infiltration of tumor cells, a few of which were of a typical "signet ring" type.

Sigmoid and Rectum.—The rectum was adherent to the uterine masses posteriorly. Its lumen was much constricted, measuring only 3 cm. in circumference. The rectal wall was

Fig. 6.—Section of the ovarian tumor under low power, showing many groups of the carcinomatous cells.

smooth external surface. The cut surface was smooth and grayish white and had a lobulated appearance along the periphery that measured 2 cm. in width, and a central core that was gray and much firmer.

In the thickened peripheral parts of the ovaries the sections showed the stroma to be very heavily and diffusely infiltrated with tumor cells. They occurred in small groups separated from one another by a few stromal cells. The signet ring cells predominated here, producing the typical picture of a Krukenberg tumor. The microscopic appearance was quite uniform throughout both ovaries.

The diagnosis was Krukenberg tumor involving the stomach, ileum, appendix, sigmoid, rectum and ovaries.

This case apparently started with symptoms of stomach dysfunction as early as April 1931, at which time the physician suspected carcinoma. The x-rays at this time showed no evidence of a malignant growth, although even this early the stomach was undoubtedly involved in the process that was later found at autopsy.

The next picture was one of rectal stricture with ulceration, found when an attempt was made to determine the cause of frequent bowel movements with incontinence. This stricture resembled the lesion found in lymphopathia venereum or in gonorrheal infection. There were no symptoms at this time suggesting ovarian

involvement, or they were completely overshadowed by the rectal distress. The rupture of the sigmoid furnished the opportunity to see the pathologic condition of the intestine and ovary, which suggested the probable diagnosis.

This case strongly suggests that the primary lesion was in the stomach, with metastases to the small intestine, appendix, sigmoid, rectum and ovaries.

The distribution of lesions in this case would suggest its having been spread by the cancer cells falling from the stomach focus into the organs of the abdomen and becoming implanted there as suggested by Erdheim and Schiller.¹⁰ The abdomen looked as if it might have been subjected to a spray of metastatic cells.

It somewhat resembled one case reported by Major in that numerous small, hard, elevated whitish plaques were noted on the wall of the stomach and intestine. Like his, my case was noted for the great amount of fibrous tissue found in many of the lesions of the stomach and intestine.

Krukenberg tumors with rectal involvement have been very rare and only a few have been found in the

Fig. 7.—Section of the ovary under high power, showing clearly the large polyhedral and rounded cells with mucoid contents pushing the nuclei to one side, giving the "signet ring" appearance.

literature. Jarcho reported a case in which there was a mass of tumor tissue in the pelvis involving the left ureter, ileum, uterus and rectum. This rectal involvement was apparently only a part of a late tumor growth into it from other pelvic organs and not a separate rectal infiltration. Hundley¹¹ cites a report of Frankl's in which the occurrence of three ovarian tumors of the Krukenberg type were noted, one originating in the rectum and two in the lower part of the sigmoid. This one case of Frankl's seems to be a definite rectal involvement of a Krukenberg tumor.

1361 Perkiomen Avenue.

ABSTRACT OF DISCUSSION

DR. JOSEPH COLT BLOODGOOD, Baltimore: More papers of this kind are needed. This paper brings to the reader practically all existing knowledge of this remarkable intra-abdominal malignant disease. It illustrates the value of frozen sections in the operating room so that the operator can be informed at any moment and at frequent intervals as to the exact condition with which he is dealing. It also shows that when a surgeon removes a tumor of an ovary he should know its nature at

once. When there is no possibility of a frozen section, the stomach should be at least palpated from the pelvic laparotomy wound. Trained pathologists in the operating room during operations are just as important as trained anesthetists. This paper brings the subject of Krukenberg tumors down to date.

DR. HARRY E. BACON, Philadelphia: In two cases of Krukenberg tumor, one of which is from a series of four collected by Dr. Gault of Temple University, the initial symptoms were referable to the sigmoid and rectum. A woman, aged

Fig. 8.—Section of the sigmoid under low power, showing the tumor infiltrating the various coats.

25, was admitted to the University Hospital in November 1930 because of nausea and vomiting. Four days later she was discharged. In June 1931 she returned complaining of pain in the rectum and frequent stools. A diagnosis was made of rectal stricture, and a colostomy was performed. In December the patient was admitted to the Philadelphia General Hospital, at which time rectal examination elicited an irregular constricting mass about 4 inches above the anal margin. The patient succumbed three months later. The necropsy showed the intestine bound together and adherent

Fig. 9.—Section of the sigmoid under high power, showing a portion of the submucosa infiltrated with tumor cells and lymphocytes.

to the pelvic organs. The left ovary was enlarged, firm and nodular. In the constriction of the sigmoid there seemed to be a generalized thickening of the serous coat. Lymph nodes of the mesentery and some of the retroperitoneal glands were enlarged but were soft and grayish pink. On the left side of the pelvic peritoneum were hundreds of small areas from 1 to 2 mm. in diameter in the subserosa. In the stomach was a diffuse infiltrating growth involving the subserosa, muscular and submucous coats, with great increase in the thickness of the wall, which resembled grossly a diffuse scirrhus car-

10. Cited by Matters.⁵

11. Hundley, J. M. Jr.: Krukenberg Tumors and Other Secondary Ovarian Carcinomas, *South. M. J.* 24: 579 (July) 1931.

cinoma (linitis plastica). The other case was that of a Negro woman, aged 41, who was referred to the proctologic clinic. She had an abscess three months before, which was lanced by her family physician and after which a discharge of pus was noted intermittently. On examination, an anorectal fistula was present. Digital examination elicited two small papillae and a circumscribed area one-half inch above the anorectal line and slightly to the left of the anterior rectal wall. The tract was excised after the internal opening had been located. The area that was thought to be inflammatory now appeared as a nodule the size of a small cherry, beneath the mucous membrane and located in the rectovaginal septum about three-fourths inch above the anorectal line. The nodule was smooth and firm. The histopathologic picture was that of a Krukenberg tumor. In checking the history, it was found that in December 1932 the appendix, right tube and ovary, had been removed. The latter was cystic. In April of the same year the patient had been operated on and a small growth found on the greater curvature of the stomach close to the pylorus. The laboratory reported carcinoma. This case is unusual. The diagnosis was initially made from the rectum. It is interesting that this patient appears healthy and free from any complaint.

DR. JULIUS FRIEDENWALD, Baltimore: In the study of cases of leather-bottle stomach or sclerosing carcinoma, the so-called linitis plastica, the histologic examination presents numerous small cells containing irregular nuclei of varying size observed especially in the submucosa in addition to nucleated connective tissue cells. These cells may occur singly or in groups and resemble epithelial cells. The cytoplasm of these cells is usually clear, with no distinct membrane and frequently large vacuoli. The vacuolated elements frequently have their nucleus pushed to the periphery, presenting the appearance of a signet ring. The cells are found in the submucosa, in the connective tissue of the muscularis especially in the areas surrounding the blood vessels. The nature of these cells has not as yet been definitely determined, but attention has been directed to them as suggestive of the epithelial cells found in the Krukenberg carcinoma. While it has been established that the linitis plastica or sclerosing carcinoma is commonly observed in males and the Krukenberg tumor only in females, the microscopic appearance of the two growths is usually quite similar, and the question arises as to whether the two are related. A number of pathologists who were consulted regarding this question were unable to give any definite decision in this respect. I am anxious to learn whether Dr. Runyon has been able to collect any data regarding the question of relationship. The histologic similarity would seem to point in this direction and Dr. Bacon's first case rather confirms this.

DR. F. G. RUNYON, Reading, Pa.: In answer to Dr. Friedenwald's question, I have not thought of the relation between these two conditions, but the stomach in my case was really a typical leather-bottle stomach. The pathologist noted it and felt it was exactly that type of stomach and resembled the one reported by Dr. Miller. I presented this paper particularly to report another case of Krukenberg tumor a little unusual in its distribution and to draw the attention of the gastroenterologist and proctologist to it on account of the possibility of their running into this type of case and probably not thinking, because it is so unusual in the literature, that it might be a Krukenberg tumor.

Case Histories and Emotional Factors.—When we consider, too, what a large and increasing proportion of our patients is suffering from purely functional disorders, the scarcity, in most histories, of information regarding possible emotional factors is often surprising. This is not entirely the interne's fault in many cases; the trouble is more deep-seated than that. The curricula of our medical schools are still mainly arranged to cover the study of the physical aspects of disease, and in our hospitals and dispensaries, where our future internes are trained, the mental factors, which may be the dominant ones in the production of the clinical picture, often receive scant notice.—Blumer, George: Some Discursive Remarks on Bedside Diagnosis, *Yale J. Biol. & Med.* 6:571 (July) 1934.

THE PROBLEM OF RADIOSENSITIVITY

MAX CUTLER, M.D.

Director of Tumor Clinic, Michael Reese Hospital; Consultant in Tumors, Edward Hines Jr. U. S. Veterans Hospital, Hines, Ill.

CHICAGO

The introduction and development of radium and x-rays as therapeutic agents in cancer has raised pertinent questions concerning the radiosensitivity of normal and neoplastic cells, which have assumed both a theoretical interest and practical importance. These problems concern the pathologist, surgeon and radiologist alike, for each is called on to render important decisions on the treatment of cancer, which involve an intimate knowledge of the established principles of radiosensitivity.

It is my purpose in this communication to present a critical summary of some of the biologic, pathologic and clinical knowledge of radiosensitivity so far as it applies to the practical problems of the treatment of cancer.

An immense literature has accumulated on this subject and much of the evidence presented is both confusing and conflicting. Some of the reasons for the state of confusion are at once obvious. Perhaps the most important is the fact that the science of radiation is relatively new. Following the discovery of x-rays and radium only about thirty-five years ago, the problem passed through a preliminary experimental period

Fig. 1.—Squamous carcinoma of the mucous membrane of the cheek, before treatment.

of physical and biologic studies that were essential to establish the fundamental basis of radiotherapy; and although the clinical application of radium and x-rays began about thirty years ago, physicians are today only beginning to approach an understanding of some of the principles of radiotherapy and their clinical application to the treatment of cancer. And so it is no simple task to elicit from the mass of data that exist in the literature that small portion which has stood the test of time from the vast amount of data that in the light of present knowledge must be discarded.

No more striking example of the rapidly changing conceptions can be presented than the question of the radiosensitivity of squamous carcinoma. With the

Read before the Section on Pathology and Physiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

exception of the French school, most workers have recorded that squamous carcinoma is a radioresistant tumor. The discrepancy was soon discovered to be entirely a matter of technic and dosage. Squamous carcinoma was designated as a radioresistant tumor at a time when a short, intense and inadequate exposure to x-rays or radium failed to sterilize it until Regaud¹ and his collaborators in Paris and Pfahler² in America established that, by protracting the treatment over a

period of days, the normal tissues can withstand much greater doses, and this change in technic has resulted in making it possible to sterilize squamous carcinoma. With present methods, squamous carcinoma fulfils all the criteria of the definition of a radiosensitive tumor, but this fact is not known to many pathologists and clinicians. I have witnessed repeated instances in which thoroughly competent pathologists designate squamous carcinoma as radio-

Fig. 2.—Same case as in figure 1 after treatment, illustrating principle of selective irradiation (sterilization of the lesion without necrosis).

resistant and equally excellent surgeons decide on the basis of such reports to perform surgical removal of a lesion that is amenable to radiation and in which present knowledge indicates radiotherapy to be the method of choice. It cannot be overemphasized that the pathologist who undertakes to express an opinion on the radiosensitivity of a tumor is assuming a grave responsibility, because the surgeon who may not be completely familiar with these matters frequently bases important decisions of treatment on such information. It is the duty of the pathologist, therefore, before passing judgment on radiosensitivity, to become thoroughly familiar not only with the established principles of radiosensitivity but also with the modern advances on this subject. That the microscopic structure of a tumor is only one of a group of factors which indicate the property and degree of radiosensitivity is now fully established. An estimate of radiosensitivity in relation to treatment can therefore be made only in consultation between the pathologist and the radiotherapist if erroneous and misleading deductions are to be avoided.

Important as are the advances that have been made in the past in the physics of x-rays and radium and in the technic of application of these agents, an even more important field of investigation has developed which deals with the physiologic and biologic effects produced in normal and neoplastic tissues that are exposed to these agents. This field of study deals with radiophysiologic principles and attempts to explain the method by which irradiation effects the disappearance

of tumor cells and at the same time preserves the normal structures.

For a period of years, studies have been made of gross and microscopic specimens of tumors removed after various forms of radiation with a special view of correlating morphologic structure with radiosensitivity and also to estimate the changes produced in tissues following their exposure to different technics and various doses of x-rays and radium. The observations of many workers along these lines constitute a source of basic information on the problem of radiosensitivity. However, it is quite evident that the response of tumors to irradiation is governed by a group of factors including physical, histologic, physiologic, pathologic and clinical, which in combination with one another determine the ultimate result. The failure to recognize the relative importance of all the principles that influence the ultimate result may lead to errors in interpretation of radiophysiologic phenomena.

In passing from purely laboratory investigations to clinical observation of lesions under the influence of radiation therapy, it soon becomes obvious that a complete understanding of the problem of radiosensitivity is quite impossible without thorough familiarity with tumors before, during and after their exposure to these agents and that the ultimate criterion and only absolute test of the radiosensitivity of a tumor is its clinical behavior. Thus, clinical observation records numerous examples of marked radioresistance in tumors which, according to microscopic study, should prove to be highly radiosensitive, and with equal frequency, a high degree of radiosensitivity may be observed when all the histologic factors indicate the presence of a radioresistant lesion. These observations emphasize the inadequacy of microscopic studies alone to predict the response of tumors to radiation therapy. The explana-

Fig. 3.—Squamous carcinoma of the mucous membrane of the cheek following incorrect interstitial irradiation, illustrating the principle of caustic irradiation with the production of radionecrosis.

tion for these apparent exceptions is in the present state of knowledge not forthcoming. There is considerable evidence that physiologic phenomena as, for example, the function of secretion, affect these results and no doubt radiosensitivity is influenced by biologic factors that give no microscopic evidence of their presence.

A decision on the choice between operation and irradiation in the treatment of a given tumor is at times

1. Regaud, C.: Radiophys. et radiothérapie 1: 443, 1930; Acta radiol 11: 455, 1930

2. Pfahler, G. E.: Surg., Gynec. & Obst. 41: 443 (Oct.) 1925.

exceedingly difficult. In many examples this decision must be based on two factors: operability and radiosensitivity. Unfortunately, the clinical signs of operability are attended by gross inaccuracies and the arbitrary division of neoplasms into operable and inoperable groups is subject to numerous fallacies. The inability

Fig. 4.—Squamous carcinoma of the penis before treatment.

to judge the extent of disease by clinical examination constitutes perhaps the most important single source of fallacy in the statistical studies of cancer.

As to the results that may be expected from radiation, adequate clinical experience, pathologic data and experimental investigations are available to indicate on the one hand the value of radiation

therapy and on the other hand the limitations of these agents in the treatment of neoplastic disease. Of the several factors that determine the success or failure in the radiotherapy of a given tumor, the factor of radiosensitivity is the most important.

A radiosensitive tumor may be defined as one that can be completely destroyed by a correct irradiation without permanent damage to the surrounding normal structures.

The complete sterilization of a tumor by radiation can be accomplished in two ways: (1) selective radiation and (2) caustic radiation.

Fig. 5.—Section of lesion shown in figure 4, showing adult squamous carcinoma.

Selective radiation—the ideal form of radiotherapy—sterilizes cancer cells without causing serious damage to the surrounding normal structures. As Regaud has pointed out, this result is possible only when some difference exists between the radiosensitivity of the cancer cells and that of the surrounding normal cells. Those tumors which possess this property are called radio-

sensitive. Most tumors fail to qualify under this principle and must be classed as radioresistant. The selectivity of radiation in the treatment of radiosensitive tumors is the underlying principle of radiotherapy and it is this factor that differentiates radium and x-rays from such methods as electrocoagulation, in which no specific or selective effect on tumor cells can be demonstrated.

Caustic radiation differs from selective radiation in that it not only destroys the tumor but seriously injures the surrounding normal tissues. This form of radiotherapy has a limited field of usefulness and is specially applicable to the treatment of the more radioresistant tumors that are not too extensive. Nonselective or caustic irradiation of radioresistant tumors when the lesion is extensive usually results in radionecrosis with sloughing, secondary infection and local recurrence. The constant aim in radiotherapy is to devise methods by which complete sterilization of a neoplasm may be effected without radionecrosis.

There are no reasons for assuming that a given tumor is equally resistant to radiation throughout its life history. On the contrary there is considerable evidence to indicate that tumors pass through alternating periods of radioresistance and radiosensitivity. Undoubtedly changes in metabolism influence response to radiation; thus Crabtree and Cramer³ have discovered recently that exposure of tumor tissues to low temperatures greatly increases the susceptibility to radium, whereas anaerobiosis results in greatly increased resistance. The results of these investigations also indicate that the biologic effect of radiation is not produced through an action on the glycolytic mechanism. These results are at variance with Packard's⁴ experiments with *Diosiphila* eggs, which indicated that lowering the metabolic rate by lowering the temperature diminished the susceptibility to radiation. Ewing⁵ is of the opinion that the intrinsic property of the cells of origin more than any other factor determines the property of radiosensitivity, and there is much evidence to support this contention. Regaud has observed that the property of secretion is antagonistic to the property of radiosensitivity and believes that the radioresistance of adenocarcinomas is possibly to be explained on this basis.

From time to time efforts have been made to influence the property of radiosensitivity. In 1909 Schwartz⁶ used compression and cooling of the tissues and in 1924 Jolly⁷ noted increased radioresistance following temporary ligation of the blood supply to certain organs exposed to radiation: Heating the tissues

Fig. 6.—Squamous carcinoma of the penis after surface irradiation, illustrating radiosensitivity of squamous carcinoma by retracted and adequate surface irradiation.

appeared to increase radiosensitivity. The introduction of some of the heavy metals such as colloidal lead has been suspected of increasing radiosensitivity of tissues, but in none of these observations has a specific effect on the neoplastic cells been demonstrated and clinical results have been equally unsatisfactory.

ESTIMATE OF RADIOSENSITIVITY

The degree of radiosensitivity of a tumor may be estimated after a consideration of certain clinical and pathologic factors. It is now fully established that the

Fig. 7—Squamous carcinoma of the right vocal cord before treatment. See figure 8

carcinomas arising from the epidermoid structures of the skin and the mucous membrane comply with the criteria of radiosensitivity. Thus epidermoid carcinoma of the skin, lip, oral cavity, including the tongue, tonsil, sinuses, pharynx and larynx, also epidermoid carcinoma of the vagina and cervix are classed as radiosensitive. The marked radiosensitivity of lymphosarcoma and the cellular forms of Hodgkin's disease and embryonal carcinomas are well known. In contradistinction to these lesions, outstanding examples of radioresistant tumors are adenocarcinoma, melanoma, fibrosarcoma and osteogenic sarcoma. Carcinoma of the breast possesses an intermediate degree of radiosensitivity.

Within the group of epidermoid carcinomas there exist notable variations in radiosensitivity. Thus the more adult, hornifying squamous form with pearl formation is more radioresistant than the nonsquamous or transitional cell type. Lympho-epithelioma, the precise histogenesis of which is not known with certainty, is highly radiosensitive. Not infrequently mixed histologic types are encountered with one or another type of cell predominating. This fact must be considered in attempting to estimate radiosensitivity from a study of small biopsy specimens.

It should be emphasized that radiosensitivity does not necessarily indicate curability, nor should radioresistance be taken to imply incurability. Thus, for example, a localized radioresistant but papillary adenocarcinoma may be caused to disappear without radionecrosis under intensive irradiation approaching a caustic dose and the patient may remain cured of the disease. Such a result is exceptional, but enough examples of this kind are available to prove the point. On the contrary, a highly radiosensitive tumor as, for example, lympho-epithelioma of the tonsil, may disappear with dramatic rapidity when the course of radiation

has been only partly administered, and the patient may die promptly of distant metastases.

Notable exceptions to the radioresistance of glandular carcinomas are encountered in malignant tumors of the thyroid, which not infrequently exhibit favorable response to radiation therapy in spite of the fact that the histologic structure indicates radioresistance according to the usual microscopic criteria.

In estimating radiosensitivity, one may consider a tumor radiosensitive when a correct maximum surface irradiation can accomplish a complete sterilization of the local lesion without permanent serious damage to the tumor bed; i. e., without radionecrosis. The complication of metastasis should not be considered in this connection, as that event is dependent on other factors entirely unrelated to the problem of local radiosensitivity.

I have been impressed repeatedly by the radiosensitivity of lesions that are papillary although the histologic structure may indicate a state of radioresistance. I have observed several examples in which papillary adenoma malignum of the rectum has disappeared under intense external radium therapy and early papillary adenocarcinoma of the rectum has undergone complete regression (no recurrence after three years) under surface radium therapy and massive external radiation, yet I have never observed the complete disappearance of lesions of a similar histologic structure when they have infiltrated deeply the underlying structures. I am strongly of the opinion, therefore, that the gross character of the lesion, more particularly its papillary or infiltrating character, may be under certain circumstances a more important guide to radiosensitivity than the microscopic appearance of the growth. The ability to eradicate superficial papillary

Fig. 8—Section showing squamous carcinoma of the larynx shown in figure 7. Sterilization of the lesion was accomplished by external irradiation, illustrating radiosensitivity of adult squamous carcinoma by protracted irradiation. The patient received 100,000 milligram hours to each side of the neck with the 4 Gm. radium pack, two treatments were given daily and consecutively for forty one days, at 15 cm. distance. The patient has been well for two years

adenoma or low grade adenoma malignum of the body of the uterus by intra-uterine and external radium therapy is another example of the radiosensitivity of papillary lesions. In a recent review of this subject, Stewart⁸ has recorded similar observations.

8 Stewart, F. W. Radiosensitivity of Tumors, Arch Surg 27: 979 (Dec) 1933.

The response of a tumor to radiation—the therapeutic test—remains the most accurate and certain clue to its radiosensitivity and constitutes an important guide in treatment. Thus an estimate of the radiosensitivity of a tumor may be made after a careful consideration of clinical, gross pathologic, microscopic and radiophysiologic factors.

RADIOSENSITIVE TUMORS

With the exception of the embryonal carcinomas, Hodgkin's disease and lymphosarcoma, the strictly radiosensitive tumors have been limited to epidermoid carcinomas of the skin and mucous membranes. Thus, the outstanding successes in radiation therapy have been accomplished in carcinoma of the skin, lip, tongue, oral mucous membrane, tonsil, pharynx, larynx and cervix. It has been noted that it is precisely in these locations that irradiation has largely replaced surgical procedures.

Success in the treatment of these lesions depends on numerous factors aside from their radiosensitivity. The most important of these factors are the extent of the disease and the correctness of radiation. As regards the latter factor, it is important to point out that the responsibility of the radiotherapist is far greater today than it has been in the past. As long as the radiotherapy of cancer was limited to the treatment of advanced and usually hopeless cancer, inadequate training and incomplete equipment could result only in a lesser palliation. Today the radiotherapist is confronted with the radiation treatment of certain forms of early cancer that are amenable to radiation but are also curable by surgery. When one fails to cure an early operable carcinoma by radiation, one must be prepared to defend one's position. Responsibility is far greater than it was in the treatment of palliative, hopeless cases. Several questions immediately arise: Was the case properly selected and suitable for irradiation? Was the treatment administered according to the most modern technic and by means of the most effective equipment? Was the failure due to an incorrect irradiation or was it due to the extent of the

Fig. 9—"Radio epidermite" following radium pack therapy. A total of 200,000 milligram hours with the 4 Gm. radium pack was administered over a period of fifty days.

disease or possibly to an unusually high degree of malignancy of the tumor? The treatment of early cancer by radium and x-rays, therefore, involves comprehensive knowledge of clinical behavior, pathologic varieties and radiophysiologic phenomena related to tumors in order to evaluate correctly and interpret properly the successes and failures of these methods.

RADIORESISTANT TUMORS

A radioresistant tumor is one that cannot be completely sterilized without serious and permanent damage to the surrounding normal tissues. Thus it is evident that radioresistance is not necessarily synonymous with incurability by irradiation. A small, localized radioresistant lesion can be cured by an intense, caustic irradiation, but such treatment causes not only a destruction of the growth but also a radionecrosis of the tumor bed. This type of irradiation is to be avoided, because in most instances the eradication of such a neoplasm is best accomplished by surgical methods. There exist, however, a group of tumors possessing an intermediate degree of radiosensitivity in which eradication of the lesion can be accomplished by a caustic interstitial irradiation without radionecrosis. The more radioresistant forms of carcinoma of the breast are excellent examples of this type.

Fig. 10—Skin healed sixty days after height of reaction.

Adenocarcinoma, melanoma, osteogenic sarcoma, fibrosarcoma and neurogenic sarcoma represent the radioresistant lesions and constitute the group that thus far has failed to respond satisfactorily to radiation therapy, but it should be pointed out that even among this group one encounters exceptions in which the relation between histologic structure and radiosensitivity fails to be maintained. Especially is this likely to occur when portions of the lesion have become anaplastic.

RECENT OBSERVATIONS IN RADIOSENSITIVITY

Regaud and Nogier⁹ and also Delbet in 1918 observed that when radiation is administered by repeated exposures over a prolonged interval the tumor cells become more resistant and develop a radioimmunity, whereas the normal cells become more radiosensitive and more subject to radionecrosis. These observations have been amply confirmed by subsequent clinical observation. Regaud in 1922, Schinz and Slotopolsky in 1926 and Regaud and Ferroux¹⁰ in 1927 demonstrated that it was impossible to cause the complete sterilization of the rabbit's testis by a single irradiation without causing serious lesions of the skin. The threshold dose for the production of radionecrosis was from 4,000 to 4,400 roentgens (Solomon) when administered in one dose and 6,200 roentgens (Solomon) when administered over a period of two weeks. At the same time the threshold of sterilization of the seminal epithelium did not increase in a parallel

⁹ Regaud and Nogier *Compt. rend. Acad. d. sc.* 158: 1711, 1914.
¹⁰ Regaud, C., and Ferroux, R. *Paris méd.* 1: 382 (April 26) 1930.

manner but remained in the neighborhood of 5,000 roentgens (Solomon) when the dose was administered in equal parts over a period of from four to nine days. Thus it was shown experimentally that by prolonging the time of treatment the threshold of cutaneous necrosis is increased by 50 per cent while at the same time the threshold of sterilization is maintained at its original level.

The saturation method of Pfahler in America resembles to some extent the technic of Coutard, although the underlying radiophysiologic principles differ somewhat in the two methods.

The experimental studies of Regaud, Lacassagne,¹¹ Nogier and Ferroux, and the clinical observations of Coutard,¹² Monod,¹³ Schintz, Pfahler, Berven¹⁴ and others have swung the pendulum from single massive doses to that of protracted and more or less continuous irradiation. The clinical results of the protracted technic in the treatment of carcinoma of the tonsil, pharynx and larynx by means of roentgen therapy recently reported by Coutard and Berven's results in carcinoma of the tonsil by telerradium therapy mark most important advances in the radiation treatment of neoplastic diseases.

According to Coutard's method the lesion is exposed to x-rays twice daily with 4 milliamperes, 200 kilovolts, 2 mm. of copper filtration, and at distances varying from 50 to 90 cm. The criterion of dosage is biologic rather than physical. Treatment is continued until there develops in the normal tissues around the lesion a condition that has been called "epithelitis."

Pursuing these general principles, I have adopted a technic of telerradium therapy that differs from the Coutard method first in utilizing the more penetrating gamma rays of radium and, secondly, in extending fully the principle of continuity of radiation. By this method the lesion is exposed to the gamma rays of radium (4 Gm. pack and 2 Gm. pack) twice daily in

way it is intended to collect and record a series of observations, which it is hoped may ultimately permit a comparison between the biologic effects and clinical results of x-rays and gamma rays. There is considerable clinical evidence to suspect that continuity of radiation may be one of the most important factors in the sterilization of neoplasms by means of radiotherapy.

One of the most important problems that confront physicians today is the question of the total interval during which radiation is best administered. There is a possibility that such an interval may vary for the different tumors. A determination of the optimal interval for each type of growth constitutes an important clinical and biologic research, which is under way at the present time.

Another factor that remains undetermined is the question of the intensity of radiation. This

is not fully established whether the optimal fraction of 100 röntgens during a period of five minutes differs from the administration of a similar dose during a period of one hour. This question raises problems that are not only of great medical interest but also of considerable scientific importance. Irradiations based on these various questions are presently being carried out at the various radiotherapy centers throughout the world.

Fig. 11—Telerradium pack, exposing carcinoma of the tonsil, with the telerradium apparatus.

Fig. 12—Course of the relation of the skin reaction following radium therapy to time of treatment and dosage.

conservative days without interruption for periods varying between twenty and thirty days. Treatment is continued until the characteristic reaction is observed in the normal tissues surrounding the growth. In this

ABSTRACT OF DISCUSSION

Dr. JAMES C. BRIDGES, Baltimore, I think that I am rather the proper person now to discuss the treatment of malignant disease by other means than surgery. I do not think that I have discussed from surgery or radiotherapy enough by the contemplation of fact. That report as my clinic told me that 45 per cent of the patients previously operated on in the clinic now are at Dr. Burdison and Dr. Hall for radio therapy. This is based on records. They are not forgettable they are all operable. They are not forgettable cases they are all forgetful but they are well under radiotherapy. This has happened during the last three years not because I have changed any but because the method of radiotherapy has changed. A great change has taken place. First of all radium

and x-rays are no longer looked on as a last resort. Dr. Hickey and I have lived through that phase of surgery when surgeons were looked on as a last resort. I never saw an appendix removed in Philadelphia when I was a surgeon. I have lived through good surgery, and I am living in the time of good radiation. Finally, the evidence that I have today suggests that the time of removing the brain for a meningioma tumor is almost over. One has to get a tumor that is of one month's duration and is smaller than a twenty-

¹¹ Regaud, E., *Radiation in neoplasms*, 1931, 1932.
¹² Coutard, E., *Radiation in neoplasms*, 1931, 1932.

¹⁴ Berven, E., *Radiation in neoplasms*, 1931, 1932.

five cent piece (24 mm.), and one has only to find it with a microscope. The chief reason for using radiation therapy will not be that one is certain that it is cancer or not, but that one is uncertain. The majority of lumps of one month's duration and smaller than a twenty-five cent piece are going to be difficult to diagnose as cancer. I remember my reaction in the beginning to the statements of Pfahler. I did not believe a word he said, but I believe them now, because when I accumulated all the cases of jaw tumors that we had in forty years, Pfahler's name stood next to all the living patients who had irradiation. He was the beginning of Coutard's method. I have seen Coutard. I have sat next to him all day long and have seen cancer of the tonsils and of the base of the tongue after five, seven and ten years. I have seen the same thing happen in Baltimore in the hands of Dr. Burnham and Dr. Neil. In cancer of the jaw I know that I have cured 10 per cent of my cases by resecting, and the patients have lived for five years, but mighty few of them are alive after ten years. I do not believe any one has faithfully studied, as I did with Dr. Halsted, beginning first in 1895, forty years ago, the actual results of what I believe can be said today to have been the best surgery. I have seen the results abroad. I saw cancer of the rectum with two great men in London. I am now seeing radiation replace surgery, certainly in the mouth. Of course, warts, skin lesions, and lesions everywhere that can be cut out can be taken off without any mutilation, with 100 per cent results. I think those cases will still be surgical. The radiotherapist has to be just as much a pathologist as the surgeon, and I don't know but that he will have to spend less time in anatomy and more time in pathology, because a pathologic point of view will give courage and direction to all who are treating cancer.

DR. J. SHELTON HORSLEY, Richmond, Va.: I cannot go quite as far as Dr. Bloodgood in repudiating surgery in the treatment of cancer, but I think there is a decided and beneficial tendency toward using irradiation rather than surgery in certain types of malignancy, such as those Dr. Cutler has shown. In many others, a combination of intelligent radiotherapy with excision is beneficial. One must bear in mind, however, that radiation is just as dangerous as a knife. If I had to choose between being operated on by an incompetent surgeon with a sharp knife and being treated by an incompetent radiologist with a powerful x-ray machine, I think I should take my chances with the knife. The indications for the proper treatment of any malignant condition should be carefully studied in every branch of clinical medicine. It is becoming more and more necessary to hitch up pathology with all clinical treatment, for clinical treatment cannot be intelligently carried on without some knowledge of the organic pathologic changes or the perverted physiology that causes the disease.

DR. E. B. KRUMBHAAR, Philadelphia: As I recall Dr. Cutler's definition of radiosensitivity, it implied that all cells of the neoplasm could be destroyed without permanent damage to the surrounding normal tissue. I believe that that would mean a cure, for if all the cells of a neoplasm are destroyed, that particular neoplasm is cured, and even if another neoplasm occurs and occurs in the same place, that is another neoplasm. In this sense, also, the term "relatively radioresistant" is meaningless. Either the tumor can have all its cells killed, or it cannot. Furthermore, I don't believe that in Hodgkin's disease it is ever clinically possible to kill the cells of the Hodgkin's lesion. Therefore, I would not agree to calling Hodgkin's disease a radiosensitive disease in this sense.

DR. MAX CUTLER, Chicago: Since there are varying degrees of radiosensitivity, it is not possible to divide all tumors sharply into two groups. The definition of radiosensitivity is therefore an arbitrary one. The definition of radiosensitivity that I have stated in this communication is that which has been proposed by Regaud and is generally accepted by workers in this field. It is based on well established biologic principles and is practically useful for clinical purposes. In stating that certain forms of Hodgkin's disease are radiosensitive I refer to the highly cellular forms which clinically and microscopically simulate lymphosarcoma so closely that a distinction between the two processes is often not possible. I wish to thank those who have taken part in this discussion.

VALUE OF FRIEDMAN TEST IN DIAGNOSIS OF INTRA-UTERINE AND EXTRA-UTERINE PREGNANCY

MORRIS A. GOLDBERGER, M.D.

UDALL J. SALMON, M.D.

AND

ROBERT T. FRANK, M.D.

NEW YORK

In a review¹ of 4,595 Friedman tests performed by twenty-six different clinical pathologists, it was shown that 5.1 per cent of the tests were false negatives and 0.95 per cent were false positives. In ectopic pregnancy 77.8 per cent were correct positives and 22.2 per cent were incorrect negatives. The technic employed in this series consisted of the injection of 10 cc. of urine into one nonpregnant mature female rabbit followed by gross inspection of the ovaries forty-eight hours later.

At Mount Sinai Hospital, 1,137 Friedman tests have been performed to date. The technic employed differs

Fig. 1.—Normal chorionic villi from ectopic pregnancy. Friedman test positive. The villus stroma, Langhans cells and syncytium are well preserved.

from that reported by others in that 20 cc. of freshly voided morning urine is used and the test is done in duplicate; i. e., two mature nonpregnant female rabbits are used for each case. Five cubic centimeters of urine is injected in the morning and afternoon on two successive days and the ovaries are inspected grossly forty-eight hours after the first injection.

With the employment of this technic in 1,093 intra-uterine pregnancies, there were six false negatives (0.55 per cent) and one false positive (0.09 per cent). The latter proved to be negative when repeated two days later and was found to be due to an error in labeling two specimens received on the same day. The smaller percentage of error in our series is probably attributable to the one essential point in which our technic differs from that generally employed; viz., the use of two rabbits for each test. The value of using two rabbits is demonstrated by the fact that, in twenty-two of our first 635 cases, one of the two rabbits was negative in proved cases of pregnancy. This would

From the Gynecological Service and the Division of Laboratories of the Mount Sinai Hospital.
1. The Friedman Hormone Test for Pregnancy, editorial, Am. J. Clin. Path. 3: 97 (Jan.) 1933.

indicate that at least 3.4 per cent of rabbits are refractory to pregnancy urine.

The value of the Friedman test in ectopic pregnancy is worthy of consideration, as it is in this type of pregnancy that the diagnosis is most often in question.

In forty-four ectopic pregnancies in which Friedman tests were done in duplicate, there were fourteen false negatives (32 per cent error). In this series, the Friedman test was considered to be of value only when it was positive. Not infrequently the diagnosis of ectopic pregnancy was made from the history and clinical observations, in the face of a negative test.

The high percentage of false negatives in ectopic pregnancy can be accounted for if one studies the histologic structure of the specimens removed at operation. In every one of these specimens examined there were either degenerated or necrotic villi. In twelve instances the villi exhibited various stages of degeneration, the majority being necrotic, appearing merely as "ghosts" (figs. 1 and 2). In one instance there was a four months macerated fetus; in another, no villi were found. The latter specimen was reported by the pathologist as a "hematosalpinx, probably an old ectopic."

Of the thirty cases of ectopic pregnancies with positive Friedman tests, well preserved villi were found in the specimens of twenty-two; villi in various stages of degeneration were found in three and no villi in five.

As the positive Friedman test is dependent on the presence in the urine of the anterior pituitary-like hormone elaborated in response to activity of the chorion, it is obvious that with death or degeneration of the chorionic villi the test will become negative. Keeping in mind the fact that quite frequently when the Friedman test is done in a case of ectopic pregnancy there has already occurred either tubal abortion or rupture, so that the chorionic tissue is either degenerated, dead

criteria the chorionic villi are classified as "degenerated" or "ghosts," there is no way of estimating whether or not these villi still have some activity. As regards the five cases with positive tests in which no villi were found, we are forced to the conclusion that the ovum and chorion were lost among the blood clots.

In this connection it is worth while remembering that in intra-uterine pregnancy the Friedman test will

Fig. 3.—Completely degenerated chorionic villi, "ghosts of villi" from ectopic pregnancy; Friedman test negative. There is entire absence of cellular structure; the villus stroma and cellular outline are hyalinized.

Fig. 2.—Degenerated chorionic villi from ectopic pregnancy; Friedman test negative. The villus stroma is beginning to disintegrate. The Langhans cell layer is incompletely degenerated; remnants of syncytium are still present.

or completely separated from the circulation of its host, the high percentage of false negatives becomes understandable.

How is one to account for the positive tests in the three cases with degenerated villi? As serial sections were not made, it is quite possible that there may have been some active chorionic tissue present which was overlooked. Furthermore, while judged by morphologic

become negative if there is either complete separation or degeneration of the chorion. On the other hand, with a dead fetus, as long as the chorion is preserved, the test will remain positive. We have found the Friedman test positive as long as thirty days after death of the fetus. Death of the fetus was determined by the disappearance of female sex hormone from the blood, as previously reported.² In another case of fetal death a positive Friedman test was obtained with as little as 0.5 cc. of urine. The curettings in this case revealed well preserved placental tissue.

The Friedman pregnancy test is a valuable laboratory aid in the diagnosis of pregnancy. Like other laboratory tests, however, it has its limitations. For the clinician, it is important to remember that a positive test means merely that the patient is excreting anterior pituitary-like hormone which is formed in response to the presence of viable chorion, that the positive test does not indicate whether the fetus is alive or dead, that the test will remain positive in missed and in incomplete abortions as long as viable chorion is attached to the uterine wall, and that a negative test does not exclude the presence of an ectopic pregnancy.

SUMMARY AND CONCLUSIONS

1. In 1,093 normal intra-uterine pregnancies the percentage of false positive Friedman tests was 0.09. The percentage of false negatives was 0.55.

2. This small percentage of error, as compared to other reports, is attributed to the fact that duplicate tests were performed.

3. At least 3.4 per cent of rabbits appear to be refractory to the Friedman test.

2. Spielman, Frank; Goldberger, M. A., Frank, R. T.: Hormone Diagnosis of Viability of Pregnancy, *J. A. M. A.* 101: 266-268 (July 22) 1933.

4. In ectopic pregnancy, the percentage of false negatives in a series of forty-four cases was 32.

5. The high percentage of negative tests in ectopic pregnancy is accounted for by the presence in these cases of dead or degenerated villi.

6. In both intra-uterine and extra-uterine pregnancies the Friedman test is dependent on the viability of the chorion.

7. In missed abortion the Friedman test may remain positive for as long as thirty days after death of the fetus.

8. In incomplete abortion the Friedman test may be positive.

9. The presence of a viable fetus can be determined by study of the female sex hormone of the blood.

10. In the diagnosis of ectopic gestation the Friedman test is of value only in cases in which it is positive.

11. If the test is negative in a case of suspected ectopic pregnancy, the clinical history and observations should determine the diagnosis.

145 West Eighty-Sixth Street.

Clinical Notes, Suggestions and New Instruments

ESTRIN IN HIGH CONCENTRATION YIELDED BY A FIBRO-ADENOMA OF THE BREAST

DEAN LEWIS, M.D., AND CHARLES F. GESCHICKTER, M.D.
BALTIMORE

Diffuse and localized hypertrophy of the breast occurs relatively frequently in both the male and the female. In gynecomastia the hypertrophy may be unilateral or bilateral, but it is usually diffuse. The unilateral type is the more common. The localized change (the so-called fibro-adenoma) is the most common form in the female breast. Diffuse hypertrophy of one or both breasts, known as virginal hypertrophy, is most frequently bilateral. Gynecomastia, fibro-adenoma, and virginal

Fig. 1.—Fibro-adenoma occurring in a Negro girl aged 12 years. Menstruation was not established. This shows a section from the mid-section of the gross specimen. The remainder of the specimen was ground and assayed for estrin and showed a concentration in excess of 5 rat units per gram of tissue.

hypertrophy are in almost all instances benign. In extremely rare instances a fibrosarcoma is supposed to have developed in or from a preexisting clinically benign fibro-adenoma.

Histologically these benign lesions are characterized by an increase in the length and diameter of the ducts, an increase

in the number of layers of epithelium lining the ducts, and a proliferation of the periductal connective tissue. The histologic picture is essentially an exaggeration of that observed in the normal female breast when puberty hypertrophy is taking place.

In the adolescent girl, normally, definite changes begin from three to five years before menstruation is established. Enough clinical and experimental evidence has accumulated to warrant

Fig. 2.—An area from the specimen shown in figure 1 showing a typical fibro-adenomatous appearance.

one in assuming that there is a direct relationship between ovarian hormones and the changes occurring at puberty. Having such a relationship in mind, we desired to determine whether estrin could be found in such tumors and, if so, in what amounts. Our observations were so striking that we feel justified in recording the following case:

A Negro girl, aged 12 years, had had no previous illness, with the exception of recurrent attacks of tonsillitis and chicken-pox at 5 years. She weighed 105 pounds (47.6 Kg.). Two years before admission to the hospital the breasts began to enlarge. The enlargement apparently proceeded normally, although the patient's mother said that she thought the breasts were unequal in size. Sometime before admission to the hospital, however, a distinct mass, which grew rapidly, was found in the left breast. This mass was not tender, and attention was attracted to it because of the size.

The girl was well developed. She had a slight scoliosis. The right breast was definitely larger than the breast of a girl of the same age normally would be. The left breast was almost twice as large as the right. It contained a nodular mass about the size of a medium size adult fist. The mass was freely movable, being attached neither to the skin nor to the underlying structures. The skin over the tumor was normal. No abnormalities of the nipple were noted. There was no discharge from the nipples.

April 23, 1934, the tumor in the left breast was removed with some of the overlying skin. Microscopically this tumor was a typical fibro-adenoma. The breast tissue surrounding the tumor showed an increase in the number and size of milk ducts and an increase in the periductal connective tissue.

The tumor, with the exception of a small section saved for microscopic examination, was placed in 95 per cent alcohol. This was sent to Dr. J. A. Morrell of the Biological Laboratories of E. R. Squibb and Sons, through whose kindness the tumor was assayed for estrin. Dr. Morrell makes the following statement concerning the assay: "The tissue contains a great deal more estrin than I had anticipated. It looks as though it contains more than 5 rat units per gram of tissue."

You will agree with me that this is rather remarkable when we find that the maximum which we can obtain from the hog's ovaries by an identical extraction procedure is about 50-75 units per pound of ovary. In other words, hogs' ovaries contain approximately one unit to every 9 Gm. of tissue, so that your breast tumor contains more than forty-five times as much estrin per unit weight."¹

Fig. 3.—Another area of the specimen shown in figure 1. The connective tissue in the tumor is compressing the ducts, which have undergone a marked hypertrophy.

Fig. 4.—Appearance under high power of the breast tissue surrounding the tumor shown in figure 1. The increased number of cell layers in the duct lining and the increase in periductal connective tissue in the tissue surrounding the tumor is possibly in response to a higher level of estrin in the blood.

Hypertrophy of the breast may be produced experimentally in both male and female monkeys by injections of estrin. Large quantities of estrin were found in the tumor just described. We believe that such an abnormal concentration may have an etiologic significance in the production of such a growth.

1. The final bio assay showed 6 rat units per gram of tissue, or nearly 3,000 rat units per pound.

THE PATHOLOGY OF AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

HENRY E. MELENEY, M.D.

NASHVILLE, TENN.

The papers by Drs. Meleney, Magath and Reed in this issue complete the series of clinical lectures on amebiasis read at the Cleveland session. The papers by Drs. Craig and Simon were published October 6, and the papers by Drs. McCoy and Chesley and by Dr. Lynch were published October 13.

Any description of the pathology of amebiasis must pay tribute to Councilman and Lafleur,¹ who in 1891 first described the lesions in detail and differentiated them from the lesions of bacillary dysentery, and to Leonard Rogers,² Kartulis,³ Kuenen,⁴ Craig,⁵ James⁶ and many others who have made contributions to the subject since that time.

The action of *Endamoeba histolytica* is fundamentally the same in all the tissues that it invades and in all susceptible animals into the tissues of which it gains entrance. This action is based on two weapons of

Fig. 1.—Earliest amebic lesion of the colon. A depression in the mucosa showing amebas in the lumen and beginning to invade and destroy the epithelium. One ameba is seen penetrating between two epithelial cells at the left, and another lies beneath several degenerated epithelial cells at the right. Kitten specimen. The amebas can be identified by their nuclei, which have a heavy ring of peripheral chromatin and a small central karyosome (nucleolus).

attack possessed by the ameba; namely, mechanical invasion by means of pseudopods and a toxin that acts directly on the tissues of the host. With these facts in mind it is possible to trace the development of amebic lesions wherever they occur and to understand the fully developed picture that is usually seen in man.

From the Department of Preventive Medicine and Public Health, Vanderbilt University School of Medicine.

Read in the General Scientific Meeting at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 12, 1934.

The author is indebted to the Department of Pathology of the Vanderbilt University School of Medicine for preparing the photomicrographs accompanying this paper, and to that department and the Departments of Pathology and Surgery of Columbia University College of Physicians and Surgeons for sections of tissue from which some of the photomicrographs were made.

AMEBIC LESIONS OF THE INTESTINE

In the first attack on the wall of the intestine, amebas are sometimes found on the surface of the mucosa in contact with epithelial cells, which show obvious toxic damage (fig. 1), or they may first be found beneath the epithelium with no apparent break in the epithelium.

Fig. 2.—Amebas congregated beneath the epithelium in the fundi of vertical glands of the colon. Kitten specimen.

This first attack may occur in a depression between rugae or in the lumen of a vertical gland, or it may occur on the surface epithelium between glands.

Having penetrated the epithelium, the amebas either advance along the basement membrane to the fundi of the intestinal glands, where they congregate and mul-

Fig. 3.—Amebas in a lymph vessel leading through the muscularis mucosae into the submucosa of the colon. Kitten specimen.

tiply (fig. 2), or they may penetrate the basement membrane near the surface of the mucosa and enter the connective tissue stroma between the glands. Here they pass down toward the muscularis mucosae, causing edema and necrosis of the tissue and dilatation, rupture or thrombosis of capillaries. Ultimately the necrosis involves the entire thickness of the mucosa. It may extend laterally over a wide area, or it may be sharply limited to a small group of glands.

The amebas in the fundi of the glands soon break through the basement membrane and join those from the stroma of the mucosa in penetrating the muscularis mucosae either through tissue spaces or in the lymph or blood vessels (fig. 3).

In the submucosa the amebas spread out in all directions between the connective tissue fibers. Their toxin causes edema, fibrin formation and degeneration of cells and intercellular fibers. The submucosa often becomes several times its normal thickness. There is little or no cellular response on the part of the host, so that few polymorphonuclear leukocytes and only moderate numbers of mononuclear cells may be found in the lesions; but when bacteria gain access to the tissues, especially gram-positive cocci, there is a marked polymorphonuclear response and the degenerating submucosal lesion takes on the appearance of a pyogenic abscess with few amebas in it. At the periphery of such a lesion, bacteria are usually absent, but numerous

Fig. 4.—Amebas in the edematous submucosa at the margin of an ulcer. Human case.

amebas are present in the advancing area of edema and necrosis (fig. 4).

Meanwhile if the lymphatics of the mucosa have been opened by necrosis, those of the submucosa may become filled with necrotic cells and bacteria, together with

Fig. 5.—Extensive mucosal lesion in colon of kitten showing lymph vessels of submucosa distended with products of the mucosal lesion.

amebas that have entered them in the mucosa. This is more strikingly seen in kittens than in man (fig. 5). In the submucosa the amebas also attack the walls of lymph and blood vessels and are often found in their lumens. Thrombosis of the blood vessels thus attacked is commonly seen.

Although amebas enter the lymph vessels and are undoubtedly carried in them to the mesenteric lymph nodes in many cases, amebic lesions in lymph nodes are practically unknown either in experimental animals or in man.

The lateral extension of the lesions in the submucosa leads to the cutting off of the circulation in the mucosa over the necrotic area. At the same time the discharge of the contents of the submucosal abscess allows the edges of the mucosa to collapse into the cavity thus formed. As the mucosa disintegrates the opening becomes larger, until an ulcer of considerable size may be developed (fig. 6). Frequently adjacent submucosal lesions coalesce, leaving a bridge of normal mucosa over a communicating channel underneath.

The muscular coats of the intestine offer a temporary barrier to the amebas, but the connective tissue septums between muscle bundles furnish paths along which the amebas reach the outer muscular coat and the subserous tissue (fig. 7). Gradually they also penetrate the muscle cells and cause edema, hyalinization and finally necrosis of this tissue. Secondary invasion by bacteria assists in the extension of the ulcer into this layer of the wall.

In the subserous tissue the amebas produce edema followed by the formation of fibrin on the serous sur-

Fig. 6—Section of human colon showing two deep submucosal lesions with overhanging margins of mucosa. Note thickness (edema) of submucosa and puslike contents of the ulcers.

face, which leads to adhesions of apposing peritoneal surfaces. If the necrotic process penetrates through the muscle layers, the serosa easily gives way and perforation occurs.

The lymph follicles of the colon play a minor rôle in the amebic lesions in man. They may, however, be invaded either directly from the surface or by amebas advancing in the submucosa, and they may become involved in the abscess-like lesions by direct extension. The amebas that enter lymph follicles from the mucosal surface advance radially toward the periphery of the follicles, and necrosis and secondary bacterial invasion follow.

The process that has been described represents the unobstructed development of the severest type of amebic lesion in the colon. Sometimes, however, in persons dying of other diseases, although no gross amebic lesions are visible at autopsy, microscopic lesions are found in tissue sections. In such lesions there may be no definite necrosis of the tissues. The glandular epithelium is usually missing in small areas, but except for the presence of amebas there is very little change in the tissues (fig. 7). Such a condition probably represents either the presence of a strain of ameba of a

low degree of pathogenicity or great resistance on the part of the host. It may be the condition that exists in some of the cases of amebiasis that present no clinical symptoms.

With the microscopic pathology in mind, one easily understands the gross lesions as seen on proctoscopic

Fig. 7.—Mild amebic lesion of human colon. No gross ulcers were visible at autopsy. The glandular epithelium has disappeared and there is beginning disintegration of the connective tissue stroma of the mucosa, but not complete necrosis. Very slight edema of submucosa, where numerous amebas are present in the tissue and lymph vessels.

examination or at autopsy. The earliest lesion consists merely of a slightly raised bright red spot of hemorrhage or hyperemia. Following this there are three main types of early lesions. The first is a shallow ulceration of the mucosa surrounded by a narrow ring of hyperemia. The second is a diffuse granular appearance of the mucosa representing many points of invasion of the amebas into the glands without visible ulceration. The third and much the most common in man is a sharply circumscribed nodular projection of the mucosa with a small depressed yellow opening in the center surrounded by a hyperemic ring and leading into a cavity containing gelatinous material. This represents the early stage of the abscess-like lesions in the submucosa.

Fig. 8—Amebas advancing in connective tissue septum between bundles of internal muscular layer of human colon. Muscle coat formed base of ulcer.

The larger ulcers vary greatly in size, shape and depth. When discrete, they often occupy the tops of rugae and extend transversely across the intestine. Their edges are raised and overhanging and the base consists of mucoid material covering the necrotic sub-

mucosa or the muscular coat of the intestine. Sloughing shreds of tissue may be loosely attached to the base of the ulcer. These ulcers often coalesce, forming large irregular areas sometimes bridged over with strands of partly necrotic mucosa. They may become very extensive, involving the entire circumference of the intestine and reaching a length of 6 inches or more. As they become deeper the inner muscular layer may be partly

Fig. 9.—Amebic abscess of human lung with pneumonia. Note the noncellular character of the exudate in the alveoli and the absence of alveolar architecture in the abscessed portion. Many amebas distributed irregularly throughout the lesion.

separated and hang in shreds from the necrotic base. Sloughing portions of the wall may be passed out with the stools. With destruction of the circulation or invasion of the serosa, a gangrenous condition develops leading to perforation of the wall. Such perforations are often several centimeters in diameter.

Where extensive ulceration occurs there is usually a general thickening of the wall of the colon due to

Fig. 10.—Amebic ulcer of the skin, showing invasion of subcutaneous fat by amebas at margin of ulcer.

edema, which is most marked in the submucosa; but if the lesions are discrete the appearance of the intestine between them may be normal.

Healing of intestinal lesions, if they have not advanced beyond the submucosa, frequently occurs. Lesions involving only the mucosa may leave no scar. Deeper lesions often lead to permanent thickening and rigidity or stenosis of the intestine. Peritoneal adhe-

sions may lead to permanent functional disturbances or to kinking and obstruction. Healing and active ulceration in different parts of the same ulcer frequently are in progress at the same time.

The distribution of amebic lesions in the colon may be general or localized. Localized lesions are found most frequently in places where stasis normally occurs. In their order of frequency these places are the cecum, the ascending colon, the rectum, the sigmoid, the appendix and the splenic and hepatic flexures.⁷ In general the most severe lesions tend to occur in the cecum but may be found as low as the sigmoid. Rectal ulcers are more often shallow.

In addition to the colon, the terminal portion of the ileum is occasionally found to be involved. It is probable that such involvement is always secondary to lesions in the colon.

AMEBIC LESIONS OF THE LIVER

The second great site of pathologic lesions in amebiasis is the liver. Amebas are undoubtedly transported to the liver from intestinal lesions by the portal blood stream. Councilman and Lafleur¹ and Rogers²

Fig. 11.—Amebic ulcer of the skin, showing amebas attacking exposed edge of epidermis.

advanced the theory that they might also reach the surface of the liver by way of the peritoneal cavity and that this was the best explanation of the frequency of single abscesses located near the surface of the liver. Such localization, however, may be due to the fact that the portal blood stream probably takes a more direct course toward the capillaries near the liver surface and thus tends to carry the amebas to such locations.

Clinically a condition termed amebic hepatitis is well recognized. This probably represents the existence of many small lesions containing amebas with the first stage of abscess formation. Such cases are usually treated with emetine and go on to recovery, which tends to confirm the diagnosis of amebic hepatitis but does not afford an opportunity to study the pathology of the condition.

The amebic liver abscess is usually single and situated in the right lobe, but there may be multiple abscesses scattered throughout the liver. If the abscesses are multiple they give rise to clinical symptoms early and are diagnosed before they reach a large size, but if

7. Clark, H. C.: *Am. J. Trop. Med.* 5: 157-171 (March) 1925.

the abscess is single it may reach a very large size before the diagnosis is made.

The smallest abscesses on section may be only a few millimeters in diameter. They are solid and white and still show some semblance of liver structure. In slightly larger ones the contents are gelatinous and yellow, and still larger ones contain a reddish brown fluid and shreds of necrotic tissue. In large acute abscesses the wall is usually ragged with no evidence of a fibrous capsule. In abscesses of long standing there may be a definite fibrous capsule. If secondary bacterial infection of the abscess has occurred, the contents are purulent.

Microscopically the picture is one of progressive necrosis of the parenchymatous cells of the liver, followed by dissolution of the connective tissue framework. The process extends radially as the amebas advance, always leaving a zone of collapsed stroma between the normal liver tissue and the completely necrotic center. Thrombosis of blood vessels at the periphery also occurs and may be a factor in the extension of the abscess, particularly toward the surface of the liver.⁴ The absence of a cellular reaction precludes the formation of pus, while the leaking of blood from exposed capillaries probably contributes largely to the reddish color of the fluid contents of the abscess. Amebas may be entirely absent from the fluid contents of a large abscess but are numerous in the wall.

A generalized central necrosis of liver lobules was described by Councilman and Lafleur, and a portal cirrhosis is sometimes found associated with amebic abscess of the liver; but it has not been determined that either of these processes is directly related to the amebic infection.

Because of the superficial localization of the liver abscess its extension to the surface of the liver is the rule, and adhesion to the adjacent viscera or parietal peritoneum is common, often resulting in perforation or direct extension outside the liver.

AMEBIC LESIONS OF THE LUNG

The third most frequent localization of amebic lesions is in the lung. Such lesions are sometimes embolic in origin but are usually caused by direct extension of liver abscesses through the diaphragm. The abscess may rupture into the pleural or pericardial cavity, but more often the lung becomes adherent to the diaphragm and extension occurs directly into the lower lobe. The right lung is usually the one involved. With the advance of the amebas into the lung, a localized pneumonia develops with rapid formation of an abscess. Such an abscess contains the mucoid or gelatinous material that is typical of amebic lesions, together with red blood cells, amebas, large mononuclear cells from the walls of the alveoli and fragments of the elastic tissue of the lung. At the periphery of the abscess is a pneumonic process, partly interstitial in type but mainly showing the alveoli filled with fibrin and amorphous material containing very few cells. Numerous amebas are irregularly distributed in the alveoli and to a less extent in the interstitial tissue (fig. 8).

The lung abscess usually opens into a large bronchus, discharging in the sputum a brownish mucoid material containing blood and amebas. If there is a direct connection with the liver, the discharge is similar to that of a liver abscess.

AMEBIC ULCERS OF THE SKIN

The fourth most frequent site of amebic lesions is in the skin and subcutaneous tissues. Such lesions may occur after the surgical drainage of an amebic abscess, after the drainage of a ruptured appendix or ruptured ulcer of the colon, from a colostomy opening or from direct extension of rectal ulcers through the anus by way of a fistula. They would probably never occur if the primary condition was recognized as amebic and drug treatment instituted.

Amebic infection of the skin usually appears about a week after surgical drainage has been performed. It is manifested by a rapidly spreading, intensely painful ulceration in which the advance is most rapid in the subcutaneous tissue leaving overhanging edges of dying skin, outside of which is a zone of erythema. The ulcer has a necrotic base covered with sloughs. Pus can be expressed from beneath the overhanging margin. Microscopically there is edema at the margin of the lesion into which amebas are frequently seen advancing in a frontal attack. Just behind them the tissue becomes necrotic, and still nearer the open ulcer colonies of bacteria are present. The amebas invade fat tissue (fig. 9) and can sometimes be seen attacking the exposed edge of the epidermis (fig. 10). In one case complicated by diabetes⁸ they were found at autopsy even within the striated muscle cells of the abdominal wall. These ulcers are always contaminated by bacteria, usually streptococci and staphylococci, which contribute to the gross appearance of the ulcers. Infiltration of polymorphonuclear leukocytes into these lesions is usually greater than is seen in lesions elsewhere in the body. Amebas are also found in the pus that can be pressed out from beneath the overhanging margin of the ulcer. Amebic ulcers of the skin are so similar in appearance to ulcers produced by bacteria alone that they should be diagnosed as amebic only by the finding of actively motile amebas containing red blood cells, and by the finding of typical vegetative forms of *Endamoeba histolytica* in biopsy sections.

OTHER AMEBIC LESIONS

Amebic abscesses of the brain have been reported, usually secondary to liver and lung abscesses. Amebic infections of the gallbladder and of the urinary bladder have been described, but there is much dispute about their authenticity. Hodgkin's disease and a certain type of chronic arthritis have also been described as forms of amebic infection, but these observations have not been corroborated and it may be stated with some degree of confidence that *Endamoeba histolytica* plays no etiologic rôle in connection with these diseases.

There are still certain questions to be answered in connection with the pathology of amebiasis. The reasons for the variability in the intensity of the lesions, the exact nature of the toxin secreted by the ameba, the possible effect of the toxin on organs other than those immediately involved, and the factors that lead to the development of liver abscesses are some of the problems that might well claim the attention of those interested in this important disease.

SUMMARY

The pathologic lesions produced by *Endamoeba histolytica* are the result of its mechanical invasion and

8. Engman, M. F., Jr., and Meleney, H. E.: Amebiasis Cutis, Arch. Dermat. & Syph. 24: 1-21 (July) 1931.

its toxic action on the tissues of the host. The toxic action is manifested by edema, fibrin formation, necrosis and dissolution, in varying degree according to the type of tissue involved. In the colon the mucosa is first attacked but the submucosa suffers most severely, and lesions may involve the deeper coats of the wall and result in perforation. There is very little cellular reaction unless bacteria invade the lesions. Occasionally very mild lesions are found in which amebas have invaded the mucosa and submucosa without producing definite necrosis. Partial or complete healing often takes place, and scar formation may lead to serious functional disturbances.

Liver abscess secondary to intestinal lesions is a common complication. Sometimes these abscesses are small and multiple, but more often they are large and single and situated in the right lobe. Extension of liver abscesses through the diaphragm into the lung is common, with development of a secondary lung abscess surrounded by pneumonia. Extension into the pleural and pericardial cavities also occurs.

Amebic lesions of the intestine or liver may also extend by direct contact into other adjacent organs or tissues. Amebic ulceration of the skin occasionally occurs following the drainage of visceral lesions or by direct extension through the anus from rectal ulcers. Amebic abscess of the brain is a rare though well recognized condition. The amebic etiology of other clinical conditions has not been established.

THE LABORATORY DIAGNOSIS OF AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

THOMAS B. MAGATH, Ph.D., M.D.
ROCHESTER, MINN.

It has been generally agreed by experts in the subject that the absolute diagnosis of amebiasis is accomplished only when *Endamoeba histolytica* has been identified in the stool, tissues or bodily discharges. To do this clearly requires a special knowledge of protozoa in general and specific knowledge of parasitic forms. Medical schools do not as a rule train physicians to diagnose these species, and only those having special training and experience are competent to make such diagnoses.

It is my purpose in this paper to outline briefly the general phases of the laboratory diagnosis of amebiasis so that the outline may serve as a general, practical guide to the subject, and to summarize the present status of various forms of examinations.

It is obvious that the most direct method of diagnosing amebiasis is finding the parasite in the stool. If the diagnosis is for the purpose of a survey and large numbers of persons are to be examined, one will of necessity proceed along slightly different lines than if the diagnosis concerns an individual presumably suffering with symptoms of the disease. Except under rare circumstances, for purposes of a survey it will be best to examine natural fecal specimens and not those resulting from the administration of a laxative or cathartic. Usually it will be necessary for the individual to bring

the specimen to the laboratory, as facilities rarely can be provided to accommodate large numbers of persons at a convenient time. The stool should be well formed, for loose or watery stools are not suitable for such surveys unless facilities are at hand for collecting the stool at the place of examination.

The most practical container is a pasteboard, paraffined, half-pint carton; on the top should be clearly marked the person's name and address, and the date the stool was passed. If medicolegal or official matters are involved, the container should bear identifying marks, and the conditions for the passage of the stool must be such that a responsible person can vouch for the fact that the specimen belonged to the person in question.

The specimen should reach the laboratory as promptly as possible, but it is not necessary for it to be kept warm. A stale, dried or moldy specimen is unsuitable, but one forty-eight hours old is usually satisfactory if it has been kept reasonably cool; under favorable conditions a longer time may be permitted to elapse. However, the sooner after passage the examination is made, the better the results.

If the purpose of the examination of a stool is to diagnose amebiasis among persons suspected of suffering from the infection, it is best to collect the specimen near the laboratory. The ideal arrangement is to have the toilet facilities immediately adjacent to the laboratory. The most suitable container in which to collect the specimens is an ordinary porcelain chamber. Either formed or loose stools are suitable, depending on the subsequent method of handling the material and on certain other conditions to be discussed later. Urine should not be passed into the chamber.

If a patient is suffering from diarrhea, the stool probably will be unformed, but if it is not, and a liquid stool is desired, it is best to administer from 1 to 1½ ounces (30 to 50 Gm.) of magnesium sulphate. This should be given about 7 a. m. and the patient instructed to eat his normal breakfast and to report to the laboratory about 8 o'clock. Usually the specimen will be passed before 10 o'clock. If the bowels are constipated, the patient should take an enema the evening before and, if the first stool after the salts is not soft, the next specimen should be examined.

Under no condition should any but a saline or non-oily cathartic be used, and oily preparations should be avoided for at least forty-eight hours preceding the test. Barium mixtures for purposes of taking roentgenograms should be avoided for at least seventy-two hours preceding the test.

If the stool is unformed, it should be examined as soon after passage as possible, preferably at once. If some delay must occur, the stool should be kept at body temperature. In no event should more than a few hours elapse before examination and, if facilities for keeping the stool warm are lacking, the examination must be made at once.

In dealing with hospital patients it requires the closest cooperation between the nursing staff and the laboratory personnel to obtain fresh, warm stools for examination and, if specimens have to be transported to other buildings, the most satisfactory method is to place the vessel containing the specimen in a specially constructed, warm, padded box. Under certain conditions it is advisable and preferable for the examiner to take his microscope to the bedside. Too much atten-

tion cannot be given to this phase of the work, for, if accurate diagnoses are to be made on loose stools, the specimen must be fresh and kept warm until the portion to be examined is placed on the slide.

It is evident from the foregoing that it is not practical to examine any but formed stools sent in by mail and, if formed stools are sent by mail, the delay must be minimal.

The number of stools it is necessary to examine in order to detect parasitic protozoa has received much attention. It must be realized that in formed stools certain parasites will rarely or never be seen, as, for example, *Trichomonas hominis*, *Dientamoeba fragilis* and *Balantidium coli*. Hence, a protozoologic examination will not be complete unless loose stools are examined. In general, it may be said that in the formed stool cysts will be found, and that in loose stools, trophozoites, although occasionally both forms are present especially in a loose stool. As a general rule trophozoites are more difficult to identify than cysts and, unless the stools are very fresh, serious errors will result in identifying trophozoites. There is a profound difference in the demonstrability of protozoa in formed and in loose stools. From a considerable number of observations by Dobell,¹ and by Carter, Mackinnon, Matthews and Smith² and others, Dobell concluded that, if a large series of patients is examined, a single formed stool from each will reveal about a third of the infestations present in the series and, further, that a minimum of six such specimens from a given patient must be negative before it can be concluded that he is not infested with *Endamoeba histolytica*. Svensson and Linders,³ in an elaborate mathematical treatment of the subject, concluded that about ten formed specimens are necessary in order to find all or nearly all of the infestations with protozoa, and then those which do not encyst will be missed. Examination of three stools per patient will disclose about 75 per cent of the infestations in a series.

Loose stools and those following a cathartic yield very different results. Under the conditions employed by Svensson and Linders, examination of a single specimen per patient yielded about 75 per cent of the infestations due to *Endamoeba histolytica* and a correspondingly high percentage of other protozoal infestations in a series.

My own observations, conducted over a period of fifteen years and resulting from more than 60,000 examinations, indicate that under proper conditions in about 80 per cent of cases, infestations with *Endamoeba histolytica* can be detected on the first examination, that in 95 per cent the infestation can be found by examining two specimens, and that in approximately all the infestation can be detected by three such examinations.

It is obvious that a given number of stools rendered loose by catharsis will yield a higher number of positive results than an equal number of formed stools, yet the reason is by no means clear. A stool that is semiliquid or liquid is more thoroughly mixed than a formed stool and hence the loose stool offers an opportunity to obtain

a better sample. However, over and above this is the clear evidence that more individual organisms are present in the loose stool than in the formed one. There are those who deny the excystation of amebas in the bowel and claim that the greater number in the loose stool is due to the sweeping out of the trophozoites by increased peristaltic action. Such an explanation is not sufficient unless one supposes that little or no division takes place normally among the trophozoites in the bowel and that the increase of water in the bowel stimulates amitotic division, since one trophozoite gives rise to only one cyst. The most logical explanation appears to be that increased moisture due to catharsis or looseness causes excystation and, hence, the increased number of trophozoites in the loose stool as compared to the number of cysts in formed stools.

It is advisable to have the entire stool from which to make preparations for microscopic examination. If the stool is formed, material should be taken from the outside as well as from the inside and, if patches of mucus, pus or blood occur, samples of these should be examined. In liquid or loose stools, material from several portions should be selected, and mucous flakes or bloody portions should be carefully noted and materials taken from such portions. In cases of amebic carriers, no special gross changes may be evident but, in acute cases, the typical stool will have dark brown streaks of mucus; the stool will be dark brick or reddish brown owing to partly decomposed blood. Sometimes flecks of bloody mucus are present, and in these flecks amebas are most numerous. Charcot-Leyden crystals are frequently present in amebic infestations, but their presence is not necessarily proof that the patient has amebiasis. In amebic stools, as a rule, there is more blood than pus and, when the reverse is true, one should think of tuberculosis or of chronic ulcerative colitis.

EXAMINATION BY DIRECT SMEAR

Microscopic preparations are made by emulsifying a small portion of the stool in a drop of saline solution placed on a clean glass slide; a coverglass is then placed over it. A dilute solution (1:1,000) of water-soluble eosin instead of saline solution may be used. This has the advantage that live amebas and other protozoa remain unstained while all other material, except fresh pus, yeast organisms and erythrocytes, is stained a pale pink, thus making a good contrast for the protozoa. A good rule to follow is to add enough stool to the diluent so that, when the coverglass is applied, one can just read news print through the slide. The emulsion should be homogeneous, and it is better to have the film too thin than too thick. Svensson and Linders recently have reported excellent results with Quensel stain, for trophic amebas, which is applied directly to the fresh preparation. A warm stage is not necessary, but the examination should be conducted in a warm room and, if the atmosphere is chilly, a desk light shining directly on the stage of the microscope will be found advantageous. The light entering the field should be reduced so the refractile amebas stand out sharply.

The amount of the sample of feces to be examined needs some discussion. One deals here with a problem in probabilities and random sampling, although if suspicious portions in the specimen can be found from which to select material, a special problem of selective sampling also enters. The rough average weight of formed stools is about 65 Gm.; if one makes a proper

3. Svensson, R., and Linders, F. J.: The Chances of Detecting Infections with Intestinal Protozoa, Acta med. Scandinav. 81: 267-324, 1934.

coverglass preparation, 22 by 22 mm., about 20 mg. of feces will be used. A rough average weight of stools following administration of salts is 170 Gm. Thus each coverglass affords about $\frac{1}{4,000}$ part of the specimen of a formed stool and about $\frac{1}{10,000}$ part of a stool following catharsis. This appears to be a small sample, but it is relatively 5,000 times more than the sample used to determine the erythrocyte count and about comparable to the sample from which urea in the blood is determined. If one examines two such preparations, although the material examined is doubled, the chance of finding a parasite is unfortunately not twice as great. Many items enter into this problem, but experience has shown clearly that one increases the chances of finding protozoa by taking samples from various parts of the stool and by making more than one coverglass preparation. If the material were homogeneous, of course, each preparation would have an equal chance of being positive, and one preparation would be as good as another. It is quite evi-

or depth of focus is greatly limited by the higher power.

In arriving at the time necessary to examine a preparation, measuring 22 by 22 mm., before deciding that it is negative one must first consider the number of fields on the slide. Allowing a 10 per cent overlap, there are about 160 fields at a magnification of 100 times. One who is experienced and is used to examining protozoa can detect the protozoa in a field if an average of nearly four seconds to the field is allowed. This means that to examine every field would require about ten minutes. If there were but one organism on the slide, it would surely be detected, since every field would be examined. Of course there is a personal factor involved as well as such factors as the evenness of the preparation and the quality of light but, since these vary so much and cannot be taken into a general calculation, computations are made on the assumption that if a protozoon should be in a field it would be seen. The accompanying table indicates the probabilities of finding a protozoon when different numbers or organisms are present in a 20 mg. sample of feces, over the ranges usually encountered. Since the area of the preparation examined and the time vary directly, one may conclude that the examination of one-fourth, one-half, or all the slide is equivalent to two and a half, five and ten minute examinations.

If there are very few organisms in the stool, such as, for example, an average of 0.1 of an organism per 20 mg. of feces, examining twice the number of preparations almost doubles the chance of finding an organism, provided the material is homogeneous. When the average number reaches a level as high as six organisms per 20 mg. of feces, however, the chances of finding an organism in a ten minute search are 0.998, or a failure of only two in 1,000 such examinations. Examining the slide only half so long or examining only half the slide still yields a chance of finding an organism in ninety-five of 100 such examinations. It is interesting to note that it would be better to spend the time on one slide rather than to divide equally the time between two slides, so far as the probability of finding an organism is concerned under the foregoing conditions, if the specimen is perfectly homogeneous as to distribution of organisms. There is another matter, however, which enters this picture and that is the fact that another sample may be better selected.

A question constantly arising is, after one has examined thoroughly a single slide or more than one slide and found no amebas, how many more slides should be examined before one may hope to encounter an organism, provided it is in the stool. These relations may be solved from the table. For example, if one examines four slides and finds no organism, one may be "sure" that there exists less than one ameba per 20 mg. of feces; if there had been as many as one per 20 mg., a single slide would have revealed the organism in 63 per cent of instances. Hence, if four preparations are negative, the concentration of protozoa in the stool is so low as to be almost impossible to detect. Similarly, if ten slides were negative, there would be less than 0.4 organism per 20 mg. of feces. Here again this presupposes a more or less equal distribution of organisms in the stool, and if special parts of the stool are selected the results will be varied. A number of interesting relations can be brought out from a study of the table, but in general one may say that if two coverglass preparations 22 by 22 mm. are examined for five minutes

Probabilities of Finding a Protozoon in a Specimen of Stool

* The calculations are based on the assumption that a single complete field contains 20 mg. of the specimen and that this is a random sample of the stool in which the organisms are mixed at random. If four fields are examined and no organism is found, there is "practical certainty" that there are fewer than fifty organisms per gram in the stool, or fewer than 2.5 organisms in 20 mg. of preparation. Similarly, if two fields are examined and no organisms found, it is "certain" that there are less than 100 organisms per gram, and so forth.

dent, therefore, that one should never examine less than two preparations, because the material is not homogeneous.

After the material is selected and on the slide, the question of how long to examine the slide, with what magnification, and with what chances of finding parasites on the slide if they are actually present are all important problems.

For the initial examination of the smear, the lowest power under which protozoa can be recognized should be used, and all searching should be done with a mechanical stage. The particular organism is then identified by further study with higher powered lenses. One is not ready to begin the actual diagnosis of species until he can "spot" protozoa under the 16 mm. objective and a $\times 10$ eyepiece ($\times 100$ magnification). Herein lies the real difference in the results among many observers. Those who work entirely with lenses of higher power miss many parasites. The field of a 4 mm. lens is one-twelfth the size of a 16 mm. lens and that of the oil immersion lens is one-hundredth the size of the low power lens. In addition, the plane

each, being sure that each field is a new field, in the vast majority of cases if no organisms are found the specimen may be considered negative, provided of course the material has been properly selected and the examiner is competent. When the material is quite evidently not homogeneous and portions contain mucus and blood, a large series of slides should be made from different parts of the specimen, and spending less time on each preparation will give a higher chance of positive examinations than thoroughly examining fewer preparations, because of the introduction of the factor of selective sampling, which outweighs in such instances the mathematical possibilities indicated in the table. Doubling the time on each preparation would not pay, but examining new preparations would yield a higher degree of accuracy. It would be better, if possible, to obtain another specimen from the patient and then repeat the process of examination.

If one examined slides with the 4 mm. objective and the $\times 10$ eyepiece, the time necessary to effect the same degree of accuracy, leaving out of consideration the difficulty of focal depth, would be about two hours for each examination. Under such conditions the slides would have to be ringed with petrolatum to prevent evaporation.

The time necessary to identify any given protozoan would vary with the ability and experience of the examiner and the nature of the organism. Flagellates and ciliates can be identified at a glance, and typical amebas do not require a very long time, but borderline forms and atypical forms may require lengthy observation and a time-consuming technic before positive identification can be made. Degenerating trophozoites give the greatest trouble and should not be too certainly identified.

IDENTIFYING SPECIES

The reader must be referred to standard textbooks and monographs dealing with the characteristics of unstained protozoa for the numerous details of their minute structure. Here it will be sufficient to call attention to a few major considerations. No one can be considered competent to diagnose the presence of *Endamoeba histolytica* unless he can identify the other four species of amebas, the four common flagellates, and one ciliate. One must be expert in recognizing cysts, precysts and trophozoites.

Trophozoites.—In the motile stage, specimens of *Endamoeba histolytica* usually are from 20 to 30 microns in diameter, but small races exist and these may have an average diameter no greater than 12 microns. The size is not a differential feature, except in a general way; *Endolimax nana*, *Iodamoeba buetschlii*, and *Dientamoeba fragilis* as a rule are smaller.

Without doubt the most striking thing about *Endamoeba histolytica* is its motion. It reminds one of the flowing of thick molasses. The important thing is its directional character, which pulls the ameba out in a bandlike form. The whole protoplasm flows along, the ectoplasm being almost unseen in rapidly moving forms. As time elapses, the motion becomes less characteristic, and explosive movements occur, with glasslike ectoplasmic blobs. The motion of all other amebas is nondirectional and not nearly so rapid, although comparison cannot be made unless one examines perfectly fresh, warm stools.

The content of the cytoplasm is a second characteristic. In *Endamoeba histolytica* the protoplasm is finely

granular and almost homogeneous. If the amebas are from a patient with an acute case, or, sometimes, from a well purged carrier, erythrocytes may be seen within the cytoplasm. These probably never are ingested by other amebas, and for practical purposes one may, with assurance, call any ameba containing erythrocytes *Endamoeba histolytica*. Other species of amebas exhibit food vacuoles and ingest all manner of bacteria, fecal debris, and even other protozoa.

The third important characteristic is the nucleus. Because of its delicate nature and the opaqueness of the cytoplasm, the nucleus of *Endamoeba histolytica* is difficult to see; but by careful focusing and adjustment of the light, one frequently can make out the delicately beaded peripheral zone of chromatin, although rarely the central, delicate karyosome. The nucleus of *Endamoeba coli* is coarse, and a ring of chromatin is easily seen outlining it. Frequently, an eccentric karyosome can be distinguished.

Other Amebas.—The other three amebas are distinctly smaller than either *Endamoeba histolytica* or *Endamoeba coli* and, as a rule, quickly lose motility. They contain food vacuoles, with bacteria, and their nuclei are rarely seen in the fresh state.

One of the most confusing things in the examination of feces is the large number of objects which may be mistaken for amebas, and only great study, careful instruction and experience can protect the observer from error. The most confusing object is probably *Blastocystis*, a harmless, yeastlike organism present in many stools. Its peripheral "nuclei," however, clearly identify it. Large macrophages and even pus cells are also frequently mistaken for amebas.

Precystic Forms.—Precystic forms are almost impossible to distinguish in the fresh state, are devoid of food vacuoles and have thin, delimiting membranes. The nuclear characteristics remain constant but can be seen only in very favorable specimens.

Cysts.—The cysts of amebas are rather readily detected in the fresh material by their clear, glasslike appearance and gray-green color. The cysts of *Endamoeba histolytica* and of *Endamoeba coli* are almost always spherical, whereas those of *Endolimax nana* are usually ovoid. The cysts of *Iodamoeba buetschlii* are frequently irregular, whereas cysts of *Dientamoeba fragilis* are described by Kofoid as being spherical. The size varies with the species; cysts of *Endamoeba coli* are the largest, as a rule averaging from 12 to 18 microns, and those of *Endamoeba histolytica* average from 10 to 15 microns, with small races averaging as little as 5 microns and large races up to 20 microns. With favorable light, cigar-shaped chromidial bars may be seen in the cysts of *Endamoeba histolytica* and, occasionally, one may count the number of daughter nuclei in the cyst. In the fully developed cyst of *Endamoeba histolytica*, there are four such nuclei, whereas in that of *Endamoeba coli* there are eight. The structure of these nuclei is like that of the motile forms. Frequently the nuclei of cysts of *Endamoeba histolytica* are near four poles, suggesting two pairs, whereas in cysts of *Endamoeba coli* the nuclei are bunched in the center of the cyst.

IODINE STAINING

As an aid in diagnosing fresh amebas, compound solution of iodine (Lugol's solution) is very helpful. This may be used either to emulsify the fecal material or to run in under the coverglass while watching a

certain ameba under the lens. If one becomes skilful in the latter technic, much time can be saved, since the organisms stain brown with the iodine and are hard to distinguish from the background. Although iodine staining may be used to bring out the nucleus of the motile form, it has its greatest usefulness in identifying cysts. The nuclei can be readily counted and, under the oil immersion lens, the character of the nuclei can be seen in some cases. In addition, the mass of glycogen can be observed. In the early stages of cysts of both *Endamoeba histolytica* and *Endamoeba coli*, diffuse masses of glycogen exist, with a more abundant amount of glycogen in cysts of *Endamoeba coli*. In older cysts, it is rare to see the glycogen. Glycogen in several diffuse masses is usually seen in cysts of *Endolimax nana* whereas in cysts of *Iodamoeba buetschlii* the discrete spherical mass of glycogen is entirely diagnostic.

One must remember that while, as Lynch⁴ remarks, the key to the diagnosis of cysts lies in the fact that those of *Endamoeba histolytica* have four nuclei and those of *Endamoeba coli* eight, at one stage every cyst of *Endamoeba coli* has four nuclei and every mature cyst of *Endolimax nana* four as well; in addition, sometimes, cysts of *Endamoeba histolytica* have more than four nuclei. It is the structure of the nucleus in the cyst that is finally determinative and not the number of nuclei alone. The fine, peripheral, beaded chromatin, and central, minute karyosome of the cyst of *Endamoeba histolytica*, as contrasted with the coarse band of chromatin, or large, heavy blobs, and heavy, eccentric karyosome, with granules between it and the periphery of the nucleus, in that of *Endamoeba coli*, are the true criteria for identification.

PERMANENT STAINED PREPARATIONS

In all cases of doubt, or when evidence is to be kept, permanent, stained slides should be made. One may, in any large routine series, expect to correct about 10 per cent of diagnoses of *Endamoeba histolytica* by properly prepared, stained slides. However, by carefully choosing the specimens for such checking, one can obtain satisfactory results by staining only a relatively few slides. As a rule, it is harder to find amebas on these slides than in fresh smears, and the labor of preparation and searching greatly discourages their general use.

Many methods have been proposed and many modifications offered, but the one most generally used and most satisfactory is iron hematoxylin staining following fixation in Schaudinn's fluid. The following brief outline gives a satisfactory technic:

1. Make a thin smear on a very clean slide and, when the edges begin to dry and while the preparation is still moist, plunge the slide into Schaudinn's fixative.
2. Fix thirty minutes.
3. Wash in running water for thirty minutes to one hour.
4. Treat slide with dilute solution of iodine.
5. Rinse.
6. Pass successively through alcohol solutions, 50 per cent, 70 per cent and 95 per cent, respectively, and harden in 95 per cent alcohol for one hour.
7. Return to water for five minutes.
8. Mordant in 2 per cent iron alum, twenty minutes.
9. Wash with six changes of water.
10. Stain in 0.5 per cent hematoxylin, fifteen minutes.

4. Lynch, K. M.: Protozoan Parasitism of the Alimentary Tract, New York, Macmillan Company, 1930.

11. Wash and decolorize in 2 per cent iron alum until nuclear detail is clear (under the microscope).

12. Wash thoroughly and to the last rinse water add a drop of ammonium hydroxide.

13. Dehydrate, using acetone in which a small amount of eosin has been added instead of absolute alcohol.

14. Place in xylene and mount in balsam. If the proper amount of eosin is used, it will greatly facilitate the identification of amebas which, not taking the eosin as readily as the background, stand out sharply against it.

By this method of staining the diagnostic details of all species of amebas are clearly revealed, and a final decision as to diagnosis may be reached when the organisms are in either the motile or the cystic stage. However, it is important to stress the point that for motile forms the slides must be fixed before the amebas have time to degenerate. Further, the diagnosis must rest, as in examining fresh material, on observing many individuals and sizing up the whole situation, it being remembered that frequently patients may harbor two or more species of amebas.

CONCENTRATION METHOD

In examining formed stools for cysts, one may advantageously resort to a concentration method. A satisfactory method is to emulsify about 2 Gm. of feces in 15 cc. of physiologic solution of sodium chloride in a conical centrifuge tube. The material should be spun for one minute at a moderate rate and the sediment in the bottom of the tube examined. If coarse particles are present in the emulsion, they should be strained out through gauze before centrifugation. One may examine the sediment either unstained, stained with iodine, or fixed; iron hematoxylin stained slides may be prepared as previously outlined.

EXAMINATION OF MATERIAL OTHER THAN FECES

Under certain conditions it will be found advantageous to examine material obtained directly from ulcers in the rectum and colon by means of the proctoscope. One should have a wire curet available and scrape out the crater of an ulcer, placing the material on a slide and applying a coverglass. If the ulcer is amebic, one will observe many organisms of *Endamoeba histolytica* in the mucus and in the bloody exudate; these are in every respect typical and usually contain numerous erythrocytes. Excellent permanent preparations may be made from such material.

Tissue for diagnosis of amebiasis may be conveniently obtained through the proctoscope, but this is rarely indicated. One may be called on to diagnose a surgical specimen or material at necropsy. Here again the demonstration of typical amebas is essential for the positive diagnosis. The type of ulcer is more or less characteristic, with its overhanging edges and undermined deep excavation. However, these characters are not sufficient basis on which to make a diagnosis, and very early lesions do not show such characteristics.

The proper fixative is Schaudinn's fluid and, after allowing from two to six hours for fixation, the material should be handled in the usual way for paraffin sections. Serial sections are not often necessary, but in any event many sections should be made. At least some should be stained with iron hematoxylin. The usual hematoxylin-eosin stain following fixation in formaldehyde is worthless and leads to serious errors.

Recently, Meriwether⁵ has used Best's stain on formaldehyde-fixed tissue with striking success, although the details of the nuclei are not so good as with iron hematoxylin staining.

If tissue is to be examined from a hepatic abscess, a part of the wall should be fixed and sectioned; the amebas will lie in the so-called intermediary zone between the pus and the injured hepatic parenchyma.

Since amebas have been found from other parts of the body besides the bowel, one may have material other than feces to examine. The amebas found in discharges from sinuses and in sputum are vegetative forms and should be sought by examining material fresh from the source. In examining pus from a suspected amebic, hepatic abscess, it should be remembered that the organisms are frequently not in the pus first aspirated from the abscess but are embedded in the more fixed and unresolved margins of the lesion, and they can be obtained only by lightly scraping the walls of the abscess. After drainage has been established, the organisms appear in the pus and can readily be demonstrated in wet smear preparations. One should remember that large pus cells and other reaction cells can resemble amebas and that rigid criteria must be applied to each object under suspicion before a positive diagnosis is made.

CULTURAL METHODS

St. John⁶ was probably the first to report making a diagnosis of amebiasis by a cultural method when direct examination of the stool gave negative results. Since then, many have reported the value of such a method. Some workers have reported finding more positive specimens by this method than by smears; for example, Craig and St. John,⁷ Bundesen and others,⁸ and Tsuchiya,⁹ who found almost twice as many cases of *Endamoeba histolytica* by the cultural method as by that of direct smear. Others, such as Magath and Ward,¹⁰ and Miller,¹¹ have reported the reverse. Still another group of investigators have reported other relations. Thus Johns and Tripoli¹² reported almost precisely checking cultures and smears in a series of cases; seven months later, however, Johns¹³ reported that of fifty cases of *Endamoeba histolytica*, in forty-nine the direct smear was positive and in only thirty-nine was the culture positive. In only one case was diagnosis made by culture and not by direct smear. Svensson and Linders diagnosed infestations of *Endamoeba histolytica* in 94 per cent of their cases by culturing a single stool following the administration of salts. They further reported growths in 84 per cent of the cases of infestation with *Endamoeba coli*, in 51 per cent of those

of *Endolimax nana*, in 60 per cent of those of *Iodamoeba buetschlii*, and in all of those of *Dientamoeba fragilis*.

Poindexter¹⁴ concluded "the cultural method as described to be superior in the interests of accurate diagnosis, because in doubtful cases *Endamoeba histolytica* may be more easily differentiated from *Endamoeba coli* in the vegetative stage than in the encysted stage." However, he did not comment on the fact that in his study he identified *Endamoeba histolytica* sixty-six times in 564 specimens by direct smear, and only fifty-three of these grew by his cultural methods, a loss in the cultures of more than 20 per cent.

A variety of mediums have been used, including such simple mixtures as salt solution and serum. A medium favored by many is a slant of liver infusion agar to which is added, as an overlaying fluid, a mixture of one part serum to seven parts of salt or Locke's solution. To this is then added a small loopful of sterile, rice starch. An egg base may be substituted for the liver-agar and egg-white mixtures in salt solution for the serum mixture. Why some workers fail to obtain uniform growth is not clear, but it is suggested that the quality of the starch may be the crux of the situation and that this question should be further investigated. The cultures reported by Bundesen and others were made from formed stools, but most other investigators have stressed the necessity for a very fresh, warm stool. Growth appears in from twenty-four to forty-eight hours. Overgrowth of harmful bacteria and *Blastocystis* frequently spoils the cultures.

The identification of the amebas in culture is by no means easy, nor have rigid criteria for their identification been as yet set up by any one. How Svensson and Linders identified so many different species is not indicated by them, and if they were correct it suggests that others have confused *Endamoeba histolytica* and *Dientamoeba fragilis* at least, if not other forms. St. John apparently depended on the motility and shape of the moving ameba, but Martin¹⁵ pointed out the marked similarity between cultured organisms of *Endamoeba histolytica* and the trophozoites of *Endamoeba coli*. Some apparently consider any ameba growing in culture as *Endamoeba histolytica*, believing that other forms rarely if ever grow. If Svensson and Linders are correct in their results, such is not the case and, if this is the sole criterion, numerous errors are likely to occur in such diagnoses. One should also remember that free-living amebas may appear in the cultures and that the utmost caution and greatest experience is necessary before one may safely identify amebas in culture; nevertheless, it is a method well worthy of utilizing.

It is evident to any one who has given consideration to the comparison of smear and culture methods that the skill and persistence of the microscopist will greatly determine how many more cultures than smears are found positive. In at least one laboratory it was evident that experience with the low power lenses resulted in finding more by direct smear than by culture when, previously, using the higher power lenses had resulted in the discovery of nearly twice as many infestations by culture as by smear.

COMPLEMENT FIXATION

The most recent method of diagnosing amebiasis is by complement fixation, described by Craig.¹⁶ The method at the present time has been limited to a few investigators and cannot be considered ready for routine application. The antigen is made by growing large numbers of amebas in cultures and making an alcoholic extract of them. After proper titration, the test is conducted along the lines of routine complement fixation tests. Craig used his antigen undiluted, and his best antigens in antigenic amounts approached closely their anticomplementary unit. This, of course, gives a small working distance, so to speak, and requires great care in setting up the test and caution in its interpretation. Tsuchiya asserted that he had made a better antigen and employed a fourth of the anticomplementary unit of a 1:100 dilution. He concluded that a negative test was significant and valuable in ruling out amebiasis, but while he stated that "a positive serologic test also seems to be quite specific in demonstrating the presence of *Endamoeba histolytica*," his protocols do not warrant such a conclusion. Of seventeen positive tests, four were in cases in which other laboratory tests for amebiasis were negative and, clinically, the diagnosis of ulcerative colitis had been made. There was one patient with amebas in the stools and a negative complement fixation test; hence, the check was actually only thirteen of eighteen patients. The error on the positive side alone was 23 per cent.

The test has great theoretical interest and warrants much more study but is not yet ready to become a routine addition to the clinical laboratory and must, for a while at least, remain in the hands of the most experienced.

SUMMARY AND CONCLUSIONS

It is evident that the laboratory diagnosis of amebiasis requires special knowledge and skill and should not be attempted except by those adequately trained and with a large measure of experience. The problems involved are quite comparable to those involving diagnosis of tissue. The diagnosis of amebiasis should be made only by those specially qualified.

The direct smear method is adequate in the hands of those properly trained in almost all cases but, if doubt exists, one should resort to fixed and stained preparations. Whether one uses formed stools or those resulting from catharsis will depend on the individual problem. Whichever is used, the limitations of the particular method must be clearly recognized.

Culture methods should be used in laboratories qualified to identify amebas, but, for the usual routine, cultures are not necessary, provided the examiner thoroughly knows how to make proper direct examinations. The cultural characteristics of various amebas growing in these cultures have yet to be clearly described, and a series of animal experiments to determine the types in a large series is greatly needed.

Until the complement fixation method is simplified, it is not suitable for routine tests.

Seventy-five per cent of infestations with *Endamoeba histolytica* can be found by examining a single stool following catharsis with magnesium sulphate, whereas only a third of the infestations will be found by examining a single formed stool. It will require from eight to ten formed stools to establish the same number of infestations as three stools following catharsis.

THE TREATMENT OF AMEBIASIS

CLINICAL LECTURE AT CLEVELAND SESSION

ALFRED C. REED, M.D.

Professor of Tropical Medicine, University of California
SAN FRANCISCO

It is my purpose to discuss the treatment of amebiasis in strictly practical terms as condensed from soundly supported scientific evidence and personal experience. No attempt will be made, therefore, to review the history or describe all the methods that have been advised. Since the introduction of ipecac into Europe in 1672, therapy has been influenced by three tendencies. In the first place, ideas of etiology and methods of diagnosis have improved. In the second place, there was a tendency to use complex formulas and substances found useful in other diseases the causes of which were biologically related, as in the case of quinine. Finally there has been the tendency to seek active principles, simple preparations and the exact methods of chemotherapeutic study, with attention to the relation between chemical structure and physiologic action.

MAJOR ANTIAMEBIC DRUGS

Leake¹ states that "few of the agents exploited for use in this condition have sufficient experimental background to justify even controlled clinical trial in human beings." He² lays down the dictum that "physicians are not justified in using new medicinals in their daily practice until . . . favorable reports have been published from trustworthy chemical, pharmacologic and clinical sources." With these criteria in view, I shall briefly summarize the chief drugs that have received widespread use in amebiasis. Leake¹ has made a pharmacologic classification of the major drugs that have been used in the treatment of amebiasis. He divides them into four groups: (I) alkaloids such as in ipecac and kurchi (cinchona might have been added), (II) organic arsenicals, such as acetarsone ("stovarsol") and carbarsone, (III) oxyquinoline derivatives such as chiniofon ("yatren") and vioform and (IV) miscellaneous antiseptics and astringents such as the alkyl resorcinols and bismuth compounds.

GROUP I

In group I, I will consider ipecac and its chief alkaloid, emetine. Quinine has been highly recommended but has not withstood the test of time. Kurchi preparations are less effective in my experience, although Acton and Chopra³ in Calcutta consider them useful. Ipecac powder plays an important part in the history of amebic therapy. Its use today is archaic and completely ignores the tendencies in therapeutics already noted. Its efficacy depended entirely on its content of emetine, which has great advantages in accuracy, ease of administration and effectiveness. The use of ipecac powder at present is therefore to be condemned entirely.

Emetine was first isolated and suggested for use in amebic dysentery by Vedder⁴ in the Philippines in

- the Hooper Foundation
Eighty-Fifth Annual
and, June 12, 1934.

1912. The following year, Rogers⁵ in Calcutta reported its clinical use in acute cases with remarkable and very quick relief of symptoms but, as later shown, amebas persisted after symptoms subsided. These results were soon confirmed by a host of observers. I will now summarize the toxic dangers of emetine and evaluate its position in present-day treatment.

It was early noted clinically that excessive use of emetine was followed by accentuation or recurrence of diarrhea, sometimes attended by nausea, by peripheral palsy and edema, and by weakness and irregularity of the heart, and that locally it was irritant to the tissues. Few adequate reports on human toxicity have been made. Leake¹ summarizes the published data to 1932 on the quantitative toxicity of emetine hydrochloride, with the average figures agreeing closely with the results of Anderson and Leake⁶ in cats and rabbits. Similar observations were made in the case of emetine bismuth iodide, emetine antimony iodide, "auremetine," and iso-amylcephaline phosphate. It seems safe to conclude that the effective dosage of all preparations containing emetine overlaps seriously the toxic range of the alkaloid. Dobell and Bishop⁷ proved this in monkey amebiasis, in which a dosage sufficient to be effective was attended by toxic symptoms in 80 per cent of the animals treated. Levy and Rowntree⁸ reported a fatality in man at a dosage of about 25 mg per kilogram. This range was the same as that reported by Leake¹ as lethal in experimental laboratory animals and by Leibly⁹ in a human case of fatal emetine poisoning. Leake¹ found a striking uniformity of lethal dosage in animals, regardless of the method of administration, except by vein, when it is many times as toxic, and regardless of whether given in a single dose or in divided doses over a relatively long time. He says: "These data indicate that emetine is detoxified or eliminated very slowly indeed, and, in conjunction with experimental and clinical observations, they point to its 'fixation' in some tissue of relatively the same functional significance in all genera, with perhaps quantitative morphologic damage, which, if extensive enough after a certain dosage, leads to such impairment of function that death may follow."

Chopra, Ghosh and De¹⁰ in 1924 concluded that emetine was a general protoplasmic poison with selective action on certain organs in the rabbit. They found that one of the earliest tissues to be affected is the parenchyma of the heart muscle, the changes being (a) cloudy swelling of muscle fibers with disappearance of transverse striations, (b) shrinkage of muscle fibers and (c) atrophy of muscle fibers and their replacement by connective tissue. They state that the occurrence of petechial hemorrhages at the site of emetine injection indicates local damage to the endothelium of the capillaries. The liver and kidneys are affected later, showing

chiefly congestion and fatty infiltration of the parenchyma. Young and Tudhope¹¹ report similar observations and in addition substantiate their claim that emetine experimentally does not affect nerves or nerve sheaths but does cause a myositis by action on muscle fiber protoplasm directly leading to muscular palsy.

Rinehart and Anderson¹² at the University of California have confirmed and extended these observations, showing that lethal or sublethal doses of emetine caused severe injury to the heart muscle in rabbits. Morphologic changes appeared after an interval of time. In animals that survived three days or longer, necrosis was seen in some fibers and degenerative swelling in the remainder. "This resulted in a rarefaction of the heart muscle and in focal proliferations of the interstitial tissue in response to the necrotic muscle fibers. A more chronic intoxication produced with divided lethal doses of emetine hydrochloride resulted in small cellular scars in the myocardium centered about necrotic muscle fibers."

It may be concluded, therefore, that emetine is unsatisfactory and dangerous for routine use for three reasons: first, because effective dosage lies within its toxic range,⁶ second, because of proved damage to the heart muscle in dosages little above therapeutic amounts, with the danger that smaller dosage may mean only a smaller damage instead of freedom from damage, and the added danger of permanent impairment due to the scarring process evoked in cardiac muscle; and, third, because of the low effectiveness of this drug in clinically safe amounts against amebas, even though it is an excellent adjuvant for relief of acute symptoms. The need for cautious administration being recognized, emetine has still an important therapeutic place in liver damage, in malignant or severe acute dysentery and in surgical amebic lesions, in which its use has two decided advantages: (a) It is much less toxic for the liver than other recommended drugs, and (b) it gives quick symptomatic control, preparing the way for more curative drugs. This opinion is supported by Craig,¹³ who says that emetine is of comparatively little value in actually curing amebiasis although most efficient in curing symptoms. Cort,¹⁴ on the basis of wide experience in Siam, believes that emetine is more specific for hepatic than for intestinal amebiasis. Johns¹⁵ considers that emetine and its compounds have at times certain disadvantages "either from the standpoint of difficulty in administration, toxicity, or ineffectiveness in establishing a permanent cure." Manson-Bahr¹⁶ believes that emetine, uncombined with other treatment, is insufficient to eradicate amebic infection, although of great value in acute stages.

GROUP II

Leake's classification of group II includes organic arsenicals. The arsphenamine type of arsenical is not considered here because of the difficulty of administration, toxicity, expense, unproved effectiveness and availability of more satisfactory arsenicals. Out of a considerable number of other arsenicals that have been

recommended or suggested on theoretical grounds, I shall note only two, acetarsone and carbarsone.

Acetarsone ("stovarsol") was probably the first organic arsenical administered by mouth as an amebicide. This report was by Marchoux¹⁷ in 1923, after this drug had been recommended for oral use in syphilis by Fournau in 1921. Acetarsone was introduced into this country in 1924 and has been widely used. However, it is too toxic¹⁸ in doses that have reasonable clinical effectiveness, and arsenic poisoning has followed its use in many cases.¹⁹

Carbarsone is a name of convenience for 4-carbamino-phenyl arsonic acid, introduced in 1932 by Reed, Anderson, David and Leake²⁰ at the University of California. It is odorless, tasteless, and highly insoluble in water but soluble in alkaline aqueous solutions. Given by mouth, it is absorbed and excreted at about the same rate as acetarsone.²¹ "Experimentally it is less toxic than acetarsone but more amebicidal, its 'therapeutic index' being about eight times as favorable as acetarsone."²² In clinical use in my service carbarsone has shown no evidence of injury to the optic tract in about 400 patients who have received it to date. "As with arsenicals generally, it is contraindicated in the presence of kidney or liver disease and hence should not be used in amebic hepatitis."²⁰ In therapeutic dosage no toxic symptoms or signs were noted in extensive and well controlled animal experiments. A total dosage of 75 mg. per kilogram of body weight can be divided into two or three doses each day for a period of at least ten days. Carbarsone has been shown to have a high therapeutic efficiency, low toxicity, availability for oral administration and low cost. These desiderata make it, in my opinion, one of the most valuable of the anti-amebic drugs.

GROUP III

The oxyquinoline derivatives offer two drugs for special consideration, chiniofon ("yatren") and vioform.

Chiniofon was introduced as a treatment for amebiasis by Mühlens and Menk²³ in 1921. It has received excellent reports from O'Connor and Hulse,²⁴ for example. Anderson, David and Koch,²⁵ however, found chiniofon not so effective experimentally as the higher halogenated oxyquinoline, vioform. O'Connor and Hulse²⁴ found that liver abscess seemed not to be affected by chiniofon orally and believed that the drug had a direct action on amebas in the intestinal tract only. The cost is considerably higher than that for other equally or more effective drugs. Craig¹² believes that chiniofon therapy requires bed rest, administration both by mouth and by rectum, and a careful diet. Its low amebicidal activity makes a large dosage necessary, about 200

0.25 Gm. pills by mouth being an average course. Two fatal cases with evidence of liver damage have been reported following the use of "yatren" intravenously in actinomycosis.²⁶ Apparently even small doses are toxic, given in this manner.

Vioform (iodochloroxyquinoline) was used on theoretical grounds in amebiasis of macaque monkeys experimentally by Anderson and Koch.²⁷ In monkey amebiasis, they report vioform to be the most satisfactory of all the common amebicides, in completely and promptly eliminating *E. histolytica*. Toxicity studies in rabbits showed no tissue damage in therapeutic dosage. In lethal amounts liver damage was found, and the drug therefore should not be used in the presence of impaired liver function. Vioform has been used in human cases of amebiasis by David, Johnstone, Reed and Leake²⁸ with results in their hands superior to chiniofon. Anderson and Reed²⁹ reported sixty cases of amebiasis treated with vioform orally. Three of these showed evidence of gastrointestinal irritation. Vioform is insoluble, but the soluble hydrochloride is irritating to mucous membranes in a concentration of 1:500. Rectal use is not recommended on this account. In the presence of gastric hyperacidity it may be that enteric coated capsules will prevent irritation. Vioform seems more satisfactory than chiniofon in amebicidal activity, in the need of a smaller dosage at less cost and in requiring neither bed rest nor rectal administration. It seems less satisfactory than carbarsone, in that it appears more apt to cause gastrointestinal irritation, seems somewhat less effective in active dysentery, and lacks the definite tonic and stimulating action of carbarsone. As an adjunct or in alternation with carbarsone it seems to fill an important place in amebic therapy.

GROUP IV

In group IV I shall consider bismuth compounds, certain alkyl resorcinols, and some astringents.

Bismuth subnitrate in massive doses has been used and recommended by many authors, notably by James and Deeks.³⁰ Anderson and Reed point out that reports of nitrite poisoning are not uncommon after ingestion of sufficient quantities of bismuth subnitrate to control diarrhea. Fatal results have been reported both in infants and in adults. Roe,³¹ in a very complete review of the subject, says: "Since most individuals can tolerate huge doses without cyanosis and since methemoglobinemia is most likely to occur in patients who have intestinal putrefaction, nitrite poisoning and methemoglobinemia appear to be dependent on the presence of certain putrefactive bacteria in the intestine, or on an idiosyncrasy to certain drugs (Sollmann, van den Bergh and Beck). Large doses of nitrates taken by mouth may produce collapse, but rectal injections of smaller doses may cause nitrite poisoning much more quickly than that from oral administration. Children

appear to be more susceptible than adults to nitrite poisoning." This conclusion is important with reference to treatment of intestinal amebiasis, in which a bacterial colitis is so prone to coexist. Bismuth subcarbonate is equally effective on pharmacologic grounds and, in my experience, avoids the definite hazards of the subnitrate. I have had no untoward effects from bismuth subcarbonate and have found it to be of definite value as an adjunct in treatment.

Of the alkyl resorcinols, heptylresorcinol was suggested in antiambic therapy by Faust.³² I was unable to confirm his results. The toxicity of this group seems to increase with increase in size of the alkyl radical.³³ Of the three readily available drugs of this series, the lowest alkyl radical, hexylresorcinol, would seem most worthy of further study. So far, results of its use in amebiasis do not seem to justify recommending it. Other astringents, such as tannates, are of definite symptomatic usefulness.

In general, the criteria of satisfactory therapy in amebiasis may be summarized as follows:²⁰ Drugs used should be clinically nontoxic, should be highly curative without adjuvants, should be available for oral administration, should interfere little, if at all, with the usual activities of the patient, and should be of low cost. These principles must receive full weight in outlining a scheme of treatment. The physician is justified only and strictly in using those drugs which most nearly fulfil these requirements.

PRACTICAL TREATMENT

In outlining an actual program of treatment, James's³⁴ dictum must be kept in mind. "Whether it is always a tissue parasite, or whether it can live harmlessly for long intervals in the lumen of the bowel, *histolytica* is invariably an enemy of its host, actively or potentially, and should be treated as such whenever and wherever found." It is assumed that spontaneous cure does not take place and that the one portal of entry is through the colon. The clinical rule should be to treat effectively every diagnosed case of amebiasis. The disease is transferred by cysts alone. Cysts must be swallowed to cause infection. Food, drink, fingers and utensils therefore offer the only means of transfer. Isolation of the patient is unnecessary, but care in personal hygiene, avoidance of fecal contamination, and clean food and drink are essential.

The scheme of treatment must be based on the colonic infection. In general, seven types of clinical picture must be considered from the standpoint of treatment to be selected: (1) dysentery with acute, malignant onset and course; (2) dysentery or diarrhea with subacute onset and course; (3) chronic amebiasis with recurring, inconstant or absent symptoms; (4) extra-intestinal abscess or ulceration; (5) complications of other diseases or of a surgical nature, and (6) sequels such as sprue, chronic simple colitis, chronic ulcerative colitis, cancer, chronic infections such as tuberculosis, and mechanical defects such as stricture. To complete the classification, a final group must be added, (7) comprising toxic results of drugs used.

1. Dysentery with acute, malignant onset and course requires immediate diagnosis and unusually prompt

treatment. Anderson and I have had excellent results with the rectal use of carbarsone,³⁵ which allows a relatively high concentration of the drug to be applied directly to the diseased area. A cleansing soda enema is followed in one hour by instillation into the rectum of 200 cc. of warm 2 per cent sodium bicarbonate solution containing 1 per cent carbarsone (supplied by Eli Lilly & Co. in 2 Gm. vials). Usually a quick sedative effect is procured by the previous administration of sodium amytal (0.2 Gm.) orally to insure sleep and facilitate retention of the enema over night. If the enema is expelled before morning, the treatment is repeated until at least five enemas have been retained over night. Prompt symptomatic relief is the rule.

If such a course is not possible, or as an alternative and less desirable treatment, emetine hydrochloride may be given hypodermically (never intravenously) in a single daily dose of 0.065 Gm. (1 grain) to a total of six doses. At the most, these six one grain doses may be followed by six doses of one-half grain (0.032 Gm.) each. The ultimate total must never exceed 10 mg. per kilogram of body weight, or 0.65 Gm. (10 grains) for a man of average weight. Other forms of emetine, and especially ipecac, are not advised.

After the initial course indicated, the treatment should proceed as described later for chronic amebiasis.

In this clinical group, often attended by fever and prostration, the patient should be in bed, on a diet of boiled milk, white bread, stale or toasted, soft cooked eggs, gelatins, tea and white rice. Feedings should be at intervals of two and one-half hours. Adequate rest should be secured by the use of sodium amytal or sodium pentobarbital by mouth or hypodermically. Symptomatically for severe colic, excessive frequency of bowel movements and bleeding, the physician may administer equal parts of either dicalcium phosphate or tribasic calcium phosphate and bismuth subcarbonate in 4 Gm. doses from three to ten times daily. Rarely atropine sulphate ($\frac{1}{150}$ grain, or 0.0003 Gm.) may be necessary hypodermically to relieve colonic spasm.

2. Amebic dysentery or diarrhea with subacute onset and course is the ordinary type. Here the need for bed rest is proportioned to the severity of bowel disturbance. It is desirable to order the same diet as given under type 1 until symptoms are controlled, after which the dietary regimen should be the same as for chronic amebiasis. Drug treatment should be exactly as outlined under type 1 to the point of relief of symptoms, at which time the treatment should proceed as described for chronic amebiasis.

3. Chronic uncomplicated intestinal amebiasis, whether a simple so-called carrier state or a condition of recurrent or mildly persistent symptoms, is the most frequent type seen in this country. Either carbarsone or vioform are to be recommended. Carbarsone is given in gelatin capsules, each containing 0.25 Gm., two or three times daily to a total of twenty doses (5 Gm.). Much larger doses have been used with no evidence of toxicity.²⁹ The course may be repeated several times, intervals of at least ten days being allowed between the courses. The urine must show no evidence of renal irritation and the liver must be free from gross damage. These precautions are necessary with both of the drugs under consideration. Except for extensive colon ulceration and severe dysentery,

33. Anderson, H. H.; David, N. A., and Leake, C. D.: Oral Toxicity of Certain Alkyl Resorcinols in Guinea-Pigs and Rabbits, *Proc. Soc. Exper. Biol. & Med.* 28: 609 (March) 1931.

34. James, W. M.: Some Observations on Intestinal Amebiasis Due to Infection with *Endamoeba Histolytica*, 16th Ann. Rep. Med. Dept., United Fruit Company, 1927, p. 185.

35. Anderson, H. H., and Reed, A. C.: Carbarsone Rectally in Amebiasis, *Am. J. Trop. Med.* 14: 257 (May) 1934.

I have not found the rectal use of carbarsone necessary. Vioform may be given in 0.5 Gm. doses in gelatin capsules twice daily for ten days. If there is evidence of gastro-intestinal irritation, it can usually be avoided by having the capsules freshly coated with melted phenyl salicylate. This course can be repeated as needed, intervals of at least ten days being allowed. Vioform should not be given by rectum. In the small group of resistant cases, alternating courses of vioform and carbarsone may be used. Repetition of treatment should await reappearance of amebas in the stools.

The diet should in general have a high protein content, low roughage and low carbohydrates. Vitamins should be high, especially vitamin B.³⁶ Dunn,³⁷ writing from a large experience in Shanghai, says that "chronic amebic cases do well, not on a restricted diet, but on a diet rich in vitamins." Many others have also made this observation. Bed rest is not necessary. Bismuth subcarbonate, with or without dicalcium phosphate, frequently makes the patient more comfortable in diarrheic episodes, especially when secondary bacterial infection plays a part, as in type 5. Short courses of irrigations of 1:2,500 acriflavine hydrochloride, given each night for five or six nights, are often useful in relieving associated bacterial infection.

4. Extra-intestinal amebiasis presents an underlying pathologic condition essentially identical with that of intestinal lesions. For practical purposes, such conditions consist chiefly of hepatitis and liver abscess. Abscess of other organs and ulceration of the skin, especially contiguous with sinuses, may require some modification of local treatment. It is probable, a priori, that in every case of intestinal amebiasis the liver is invaded. But unless a frank hepatitis is present, or unless the pathologic process has advanced to the abscess stage, general treatment as already outlined is efficient to control it. In abscess or frank hepatitis, emetine is the drug of choice and should be administered as described under type 1. The subsequent treatment medicinally is the same as in chronic amebiasis. Local treatment of amebic abscess should consist of aspiration, repeated as needed, and irrigation with 1:2,500 solution of emetine hydrochloride. Cort¹⁴ advises this procedure and states that if the fever disappears after emetine treatment it may be concluded that there is no secondary infection and therefore no need for open operation. In obscure cases, Cort advises the use of emetine as a therapeutic test.

5. Amebiasis may be complicated by other infections, by systemic diseases and by surgical conditions. In such cases the drug of choice must be selected with the entire clinical picture in view. For example, emetine would be used cautiously or not at all in the presence of myocarditis. Arsenicals would be used with caution in the presence of gross liver or kidney damage, optic nerve lesions and history of arsenical dermatitis.

With regard to complicating infections, it is to be remembered that bacillary dysentery may coexist and that the presence of some other disease of the bowel, such as cancer, may be masked by the amebic infection. There is reason to believe that amebic ulcerations of long standing may act as do other foci of infection, affording a portal of entry for bacteria, bacterial products and possibly also other chemical substances from the intestinal canal.

Surgical complications are not at all uncommon, especially in the wake of the recent Chicago outbreak. Proper treatment rests on early diagnosis, especially before or at the time of surgical intervention in the abdomen. Intensive emetine treatment is to be avoided before operation, because of the danger of weakening the myocardium. Careful diagnosis will often decide whether a moderate course, not to exceed 5 or 6 grains (0.3 or 0.36 Gm.) of emetine, should be given, or whether the emetine should begin immediately before or after the operation. Only good clinical judgment, with clear recognition of the possibilities of amebic lesions in the absence of discoverable amebas in the stools, will enable the physician to decide on wise therapy. But certainly he must have in mind the frequency with which amebic lesions simulate peptic ulcer, cholecystitis, perforation, appendicitis, gangrene and new growth, and also the extreme danger of operations involving the gastro-intestinal tract when amebic lesions are present and untreated. In this group of surgical complications, emetine is the drug of choice because of quickness of action, to be followed at the earliest safe moment by carbarsone. Surgical complications of amebiasis and amebic granulomas have been well discussed by Connor,³⁸ Gunn and Howard,³⁹ Gilman⁴⁰ and Hines.⁴¹ It is to be remembered that surgical complications may appear early in a first acute attack or late in cases insufficiently treated; also that they may be discovered unsuspected at operation, or operation may be done without recognition or under a wrong or incomplete diagnosis. James³⁰ and others have advised "wide open cecostomy and thorough irrigations through the cecostomy and through the rectum as well It was found to be very effective in the acute fulminating types and also in the chronic types that did not yield to other treatment." Dudley Smith of San Francisco strongly advises a cecostomy, after the manner described by Phillips⁴² of Los Angeles.

6. Sequels of amebiasis include sprue, chronic simple and chronic ulcerative colitis, cancer, chronic infections such as tuberculosis, residual ulceration and colitis maintained by secondary bacterial infection and mechanical disturbances such as scarring and stricture. These are to be considered separately by Dr. Lynch⁴³ and are noted here only for the sake of completeness. It is particularly to be noted that effective treatment early in the course of amebic infection is important in preventing such sequels.

7. The final clinical point needing attention from the point of view of treatment simply crystallizes what has been covered already in respect of the need of avoiding extra hazards from the drugs themselves. Anderson⁴⁴ has discussed this in detail. It is worthy of repetition that the best treatment will approach most nearly the following criteria: high clinical effectiveness, low toxicity, amenability to oral administration, noninterference with the usual activities of the patient, lack of need for adjuvant treatment, and low cost.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
H. A. CARTER, Secretary.

HANOVIA HOME MODEL ALPINE SUN LAMP ACCEPTABLE

This is a quartz mercury vapor arc lamp designed for prophylactic ultraviolet radiation applications and manufactured by the Hanovia Chemical and Manufacturing Company, Newark, N. J.

The Home Model Alpine Sunlamp is available in two forms, one for direct current, the other for alternating current. They operate on a 110 volt circuit.

The two lamps employ the same hemispherical polished aluminum hood and reflector mounted in such a way that the radiations may be projected downward or outward. The opening of the hood is $8\frac{1}{2}$ inches in diameter, and at 36 inches the radiation covers a circular area about 30 inches in diameter.

The lamp comes either as a table model or as a stand type model. The stand type lamp is mounted on casters and is provided with vertical adjustment.

The electrical controls of the alternating current lamp are contained in a separate housing 9 by 7 by $8\frac{1}{2}$ inches, weighing about 35 pounds. For the stand type lamp the electrical housing is mounted on the base. A double pole snap switch is provided on the lamp cord. The electrical circuit for the alternating current lamp consists of a transformer and reactor, with a small rheostat for line voltage adjustment, and ballast.

The light generator consists of a two electrode highly evacuated tubular vessel constructed entirely of fused quartz for direct current. This burner operates on either polarity. For alternating current a three electrode burner constructed entirely of fused quartz is employed. Both burners employ the fused-in wire seal.

The lamp is lighted by turning on the electric supply and tilting the burner for the establishment of the arc.

The Home Model Alpine Sun Lamp produces a characteristic quartz mercury arc spectrum with a spectral energy distribution closely resembling that previously given for the physician's therapeutic lamp, the Super Alpine Sun; however, since the electrical energy input is less, naturally the emitting radiation energy is less.

At a distance of 36 inches between the recipient with an average skin and the lamp, no more than fifteen minutes should be required to produce a perceptible erythema.

Suitable eye-protecting goggles must be worn when the Home Model Alpine Sun Lamp is employed.

Operating Characteristics

Alternating Current, 60 cycle (25 cycle requires special equipment)		Direct Current	
Line voltage	100 to 125 volts	Line voltage	100 to 125 volts
Starting amperage	5 amperes	Starting amperage	4 amperes
Operating amperage	2.9 amperes	Operating amperage	2 amperes
Wattage	300	Wattage	140
Burner voltage	135	Burner voltage	70
Burner wattage	200		

Note: The direct current lamp has two thirds the intensity of ultraviolet of the alternating current lamp.

Based on evidence that radiations from the mercury vapor arc in quartz lamps at the prescribed distance (36 inches) may prevent rickets and aid in the development of sound bones and teeth, the Council on Physical Therapy declares the Hanovia Home Model Alpine Sun Lamp acceptable for inclusion in its list of accepted devices for one year.

Hanovia Home Model Alpine Sun Lamp.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

- (1) CEDAR HILL BRAND GOLDEN SYRUP
- (2) CEDAR HILL BRAND WHITE SYRUP
- (3) UNCLE SAM BRAND TABLE SYRUP
- (4) PRESIDENT BRAND TABLE SYRUP

Distributors.—(1) and (2) Hassendeubel Grocery Company, St. Louis.

(3) and (4) Gildehaus, Wulff & Co., St. Louis.

Packer.—Union Starch and Refining Company, Granite City, Ill.

Description.—(1) Table syrup; corn syrup flavored with refiners' syrup. The same as Golden Drip Brand Golden Table Syrup (THE JOURNAL, May 26, 1934, p. 1763).

(2) and (4) Table syrup; corn syrup sweetened with sucrose; flavored with vanilla. The same as Union Brand Crystal White Syrup (THE JOURNAL, Sep. 3, 1932, p. 833).

(3) Table syrup; corn syrup flavored with refiners' syrup. The same as Union Brand Golden Table Syrup (THE JOURNAL, July 23, 1932, p. 309).

GOOD MORNING PURE FLORIDA GRAPEFRUIT HEARTS

Distributor.—Chas. W. Bauermeister Company, Terre Haute, Ind.

Packer.—Dr. P. Phillips Company, Orlando, Fla.

Description.—Canned sliced Florida grapefruit sweetened with added sucrose and retaining in large measure the original natural vitamin content; the same as Dr. P. Phillips Florida Fanci-Cut Grapefruit Slices (THE JOURNAL, Nov. 19, 1932, p. 1781).

MONTCO STERILIZED EVAPORATED MILK

Distributor.—William Montgomery & Company, Philadelphia.

Packer.—The Defiance Milk Products Company, Defiance, Ohio.

Description.—Unsweetened, sterilized, evaporated milk. The same as Defiance Pure Evaporated Milk, THE JOURNAL, March 3, 1934, page 693.

FONTANA'S EGG NOODLES FINE FONTANA'S EGG NOODLES WIDE FONTANA'S EGG VERMICELLI FIDEOS

Manufacturer.—Fontana Food Products Co., San Francisco.

Description.—Noodles prepared from flour and egg yolk.

Manufacturer.—The flour, egg yolks and water, in definite proportions, are mechanically mixed and kneaded. The resulting dough is rolled by machine to required thinness, cut, dried on racks under controlled conditions, and packed in cartons.

Analysis (submitted by manufacturer).—

	per cent
Moisture	12.4
Ash	0.6
Lipids	5.7
Protein (N X 6.25)	13.0
Reducing sugars as dextrose	0.8
Sucrose	0.3
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	68.1
Lipid phosphoric acid as P ₂ O ₅	0.13
Total phosphoric acid as P ₂ O ₅	0.41

Calories.—3.8 per gram; 108 per ounce.

Claims of Manufacturer.—Complies with the United States Department of Agriculture definition and standard.

PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

For eight years the Council on Medical Education and Hospitals with the assistance of the committee of pathologists and of the local advisers has prepared lists of approved clinical laboratories and physicians specializing in pathology and clinical pathology. This work was begun by the Council in 1924 according to instructions received from the House of Delegates. In 1931 the listing of approved clinical laboratories as such was discontinued and a list of physicians specializing in pathology substituted. The laboratories supervised by the physicians listed may be said to be approved.

The original request for some regulation regarding clinical laboratories came from the clinical pathologists in 1923, the American Society of Clinical Pathologists and the American Association of Pathologists and Bacteriologists having worked independently for some time toward a solution of the problem. Some means of eliminating lay specialists in this field was sought. It was held improper for any person not qualified educationally and legally to assume the responsibility of making a diagnosis or prognosis, or of acting as a consultant with regard to disease in the human body. Where the law does not restrict diagnosis and the interpretation of laboratory observations to qualified medical practitioners, all other means available should be used to protect the patient against the incompetence of the lay specialist and the nonmedical clinical laboratory.

In order that patients may be given the benefit of the most accurate analysis with regard to source, nature and progress of disease, physicians should have their work carried out in laboratories under the supervision of capable pathologists. The progress made through the efforts of the Council, to distinguish medical from nonmedical laboratories and to determine which laboratories under medical supervision were to be relied upon, has been proportionate to the cooperation extended by the profession generally. Doubtless, this work has been responsible to some extent for the decrease in the use of lay-supervised clinical laboratories and has brought to many physicians an appreciation of the full importance of medical supervision over this work.

The present list of physicians specializing in pathology and clinical pathology contains 795 names. The first list published in 1926 contained the names of 162 laboratories. The list has grown at the rate of approximately 100 names per year. Physicians everywhere are urged through the publications of the Council to patronize only such laboratories as are under the direction of physician-pathologists, listed or eligible for listing. Applications for recognition on the approved list are being considered regularly by the Council and the local advisory committees.

In 1928 the Section on Radiology requested the Council to carry out a similar work for radiologists. A list of physicians specializing in radiology is also maintained by the Council in the same manner as the list for pathologists and clinical pathologists. At the present time, 1,270 radiologists have been admitted to the Council's list.

BIBLIOGRAPHY

The initial steps, beginning with the authorization of the movement by the House of Delegates of the American Medical Association at the annual session in San Francisco in 1923, are given in *THE JOURNAL*, April 3, 1926. That article contains the names of the members of the joint committee and gives a detailed account of the work of the committee and the Council on Medical Education and Hospitals during the years 1923, 1924 and 1925. It contains a copy of the original questionnaire and the compilation of statistics on clinical laboratories gathered from all states of the Union by means of that questionnaire. Of special importance are the principles stated by the joint committee at that time—important because most of them still hold good, yet some of them would hardly be regarded as pertinent at the present time. The first provisional list was published in the report just referred to. Subsequent developments in the evolution of the list, the present method of preparation and particularly the changes in the list itself, are reflected in the following references:

The second publication of the list appeared in *THE JOURNAL*, March 12, 1927, and contained 145 names; the list was next published in the Tenth Edition of the American Medical Directory in May 1927 and contained 145 names; in *THE JOURNAL*, March 24, 1928, 160 names; March 30, 1929, 174 names; in the Eleventh Edition of the American Medical Directory, July 1929, 175 names; in *THE JOURNAL*, March 29, 1930, 178 names; May 23, 1931, 183 names, and in the Twelfth Edition of the American Medical Directory, June 1931, 183 names; in *THE JOURNAL*, Oct. 22, 1932, 538 names; in *THE JOURNAL*, Oct. 14, 1933, 704 names.

The following list in this issue contains 795 names.

ESSENTIALS FOR THE LISTING OF PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

Admission to the list is open to all physicians in pathologic work in accordance "whether connected with a hospital or not. The work of compiling a list of qualified pathologists according to these "Essentials" is done by the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

Definition.—A physician holding himself out as a specialist in pathology may be defined as follows: One who is a graduate in medicine having had satisfactory training and experience in pathology, chemistry, bacteriology or other allied subjects for at least three years subsequent to graduation, who is in good standing and has been duly licensed to practice medicine.

Qualifications.—(a) The pathologist shall be on a full or part time basis with a laboratory for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods, for the purpose of ascertaining the pres-

ence, nature, source and progress of disease in the human body. He should devote the major part of his time to work in this field.

(b) Pathology should be practiced on the same scientific and ethical basis, whether in the hospital or in a detached laboratory. The work represents the practice of medicine as in other specialties.

The pathologist may make diagnoses only when he is a licensed graduate of medicine, has had satisfactory training and experience in pathology for at least three years subsequent to graduation from medical college, is reasonably familiar with the manifestations of disease, and is competent to make reliable reports.

(c) Assistant: The pathologist may have a corps of qualified assistants and technicians, responsible to him, and for whom he is responsible, to carry out promptly, intelligently and accurately the several kinds of service the laboratory offers. All their reports, not only of tissues but also of all bacteriologic, hematologic, biochemical, serologic and pathologic data, should be made to the pathologist.

Scope.—A general pathologic laboratory should be prepared to render the following services:

(a) Hematologic: Blood counts, blood groupings and coagulation tests, and tests for blood parasites in general.

(b) Biochemical: Qualitative and quantitative analyses of urine, blood, gastric contents, body fluids, feces, intestinal contents and cerebrospinal fluids; renal and hepatic function tests and basal metabolism.

(c) Bacteriologic: Bacteriologic diagnoses; preparation of vaccines and blood and body fluid cultures.

(d) Serologic: Serologic diagnoses; agglutination, complement fixation, or precipitin and lysis tests.

(e) Pathologic: Preparation of paraffin, celloidin or frozen sections, microscopic and gross pathologic specimens and necropsies.

(f) Parasitologic: Protozoal and zoological diagnoses.

(g) Metabolic: Disorders of metabolism.

(h) Cardiologic: Disorders of the heart.

It is of course not expected that the candidate shall be prepared to render all the services mentioned, since the work must necessarily be diversified in larger laboratories and in smaller laboratories it is not always practical to have equipment and setups that would be

used only occasionally. Since many pathologists limit their work to one branch of the specialty, referring certain items, far more efficiency is to be expected.

Reports.—Reports should be made solely to the physician in charge of the patient and should be signed by the pathologist. All blanks and reports should have the name of the director printed on them and, if of a diagnostic or prognostic character, the name of the staff physician also.

Records.—Full records of all examinations made by the pathologist, suitably indexed and filed, are essential. Every specimen analyzed in the laboratory should be given a serial number, which should follow that specimen in the records and reports. When the laboratory report concerns a hospital patient, an exact transcript of the laboratory record should be appended to the hospital case record. Each specimen submitted to the laboratory should be accompanied by pertinent clinical data.

Library.—The laboratory should be provided with, or have convenient access to, a library including current scientific books and journals on all the various subjects required in its work.

Fees.—There should be no dividing of fees or rebating between the laboratory or its pathologist and any physician, corporate body or group.

Publicity.—Publicity should be in professional good taste and be limited to statements of fact, as the name, address and telephone number of the laboratory; names and titles of the pathologist and other active responsible personnel; fields of work covered; office hours; directions for sending specimens, and the like, and should not contain misleading statements or claims of unusual superiority. It should not advocate medical fads nor lay undue stress on the importance of laboratory observations.

Only the names of those rendering regular service to the laboratory should appear on letterheads, or any other form of publicity, as being connected with the laboratory.

Advertising matter should be directed only to physicians either through bulletins or through recognized technical journals, and never to the nonprofessional public, as, for example, by announcements in popular journals and periodicals, circulars, pamphlets, telephone lists or other means.

PHYSICIANS SPECIALIZING IN PATHOLOGY AND CLINICAL PATHOLOGY

The following list contains the names of 795 physicians specializing in pathology, laboratory diagnosis or clinical pathology, who returned the questionnaire, who were found to meet the "Essentials" and were recommended by the Council's advisers. Those engaged in teaching, research and other activities are admitted, as well as those in active practice. For the list of physicians specializing in pathology in government service, see page 1235.

SATURDAY, OCTOBER 20, 1934

THE TREATMENT OF MUSCULAR DYSTROPHY WITH GLYCINE

The idea of treating muscular dystrophy by the administration of glycine resulted directly from chemical analysis of the urine. The fact that the method is not yet definitely established as clinically successful in the present form of application does not detract from the essential importance of the fundamental observations. Creatinuria has been noted in many diseases that primarily or secondarily attack the muscular system. This led Thomas and his co-workers to investigate the effect of prolonged administration of glycine on the clinical course of progressive muscular dystrophies. In their preliminary report it was stated that the ingestion of from 15 to 20 Gm. of glycine daily raised the creatinuria of different cases by different degrees, depending on the extent of the original creatinuria. After some weeks the creatinurias were found to decrease despite the continuance of glycine. Coincident with the decrease in the creatinuria there was a rise in the creatinine output and an improvement in the patient's ability to hold ingested creatine. It was also reported that simultaneously the patients improved clinically.

Cuthbertson and MacLachlan¹ recently reported the results of prolonged glycine administration in nine cases of muscular dystrophy of different types and in two other cases exhibiting selective muscular atrophy. The conditions of observation were controlled as carefully as possible. There was no massage, and no electrical or tonic treatment was given, but the patients were allowed to be up and encouraged to exercise according to their powers. They were placed on a basal diet free from meat, meat extract and fish. The total creatinine and preformed creatinine outputs were estimated in the twenty-four hour specimens of urine. The difference between the two estimations represented the quantity of creatinine excreted. At various intervals the patients' reaction to ingested creatine was determined. During

these periods no glycine was taken. The amounts excreted were expressed as milligrams of nitrogen daily. Glycine therapy was usually started about three or four days after the first dose of creatine. The adults received 15 Gm. daily, the children 10 Gm. daily, dissolved in milk. Generally speaking, the greater the muscular incapacity the greater the degree of creatinuria and the less the excretion of creatinine.

In testing the reaction to the ingestion of creatine, 4.4 Gm. of anhydrous creatine was taken in one dose by the adults and 2.64 Gm. by the children. In the cases of muscular dystrophy the initial retentions of ingested creatine varied from 41 to 60 per cent of the intake in adults and from 42 to 78 per cent in the children. In the two cases of muscular atrophy the percentage retentions were 59 and 44. Following glycine therapy a definite increased retention capacity was noted in only one case of dystrophy. Four showed definitely diminished retention capacities. In three there was a definite coincident increase in the creatinine excretion. Following the ingestion of glycine, the creatine excretions increased in all the cases of dystrophy, in some to three or four times their basal values. These maximum periods of creatine excretion occurred during the first three weeks of therapy. The maximum daily creatine excretions in the various cases did not always occur in the period of maximum excretion, though this was usually the case. Following these periods of maximum excretion the daily excretions of creatine generally fell in some instances to below the basal level. Subsequent readministration of glycine after an intermission was usually accompanied by an increased creatinuria.

Clinically, five of the nine cases of muscular dystrophy were of the pseudohypertrophic type. With one exception the cases belonging to the dystrophy group showed definite general improvement as evidenced by increase in weight, gain in strength and feeling of well being. None of the patients became worse. In the majority there was also some evidence of improvement in the power of some of the specific muscles affected, but this was least in the pseudohypertrophic group. The Glasgow workers believe that in the majority of the cases the changes were in excess of those which might be expected to occur from hospitalization alone but that the term "cure" cannot be applied to the end results.

In another investigation on the same subject, the Linnewehs² attempted to study the question of possible glycine deficiency in muscular dystrophy. Their work was based on the studies of Magnus-Levi, Lewinski and Quick which demonstrated that a portion of benzoic acid, when ingested in large doses, is excreted as glyconic acid monobenzoate instead of quantitatively as hippuric acid and that the appearance of this reducing substance in the urine is a sign of glycine poverty of the

2. Linneweh, W., and Linneweh, F.: Zur Frage des Glykokollmangels und der Glykokolltherapie bei progressiver Muskeldystrophie, *Deutsches Arch. f. klin. Med.* 176: 526 (July 9) 1934.

organism. Two patients with unquestionable progressive muscular dystrophy and one normal person were investigated in this manner under controlled conditions of diet. The glycine supply and the glycine building power of the body were thus determined by the benzoic acid tolerance and it was established that no difference from the normal organism existed in this respect; therefore no true glycine deficiency exists. Consequently, glycine therapy is not a form of substitution therapy and its mode of action remains uncertain.

Careful chemical and clinical studies are gradually clarifying the underlying scientific and practical applications of an undoubted consistent chemical abnormality. Scientific medicine may again congratulate itself on the fruits of a well established mode of investigation.

"THROW-AWAY" MEDICAL PERIODICALS

The little magazines sent without subscription charge to various classes of readers are an interesting phenomenon. The complete costs of publication are of course borne by the advertisers. As might be expected, there is none too rigorous a control over the nature of goods advertised or the claims made in the advertising. Most of the advertising in such publications consists of the promotion of materials that could not possibly be accepted by the various councils and committees of the American Medical Association. A survey made of one of the most widely circulated free publications showed 85 per cent of the goods advertised as unacceptable to these rating bodies. From this point of view, then, these periodicals are a vicious menace to the high standards of medical practice in this country.

The "throw-away" called "Medical Economics" has appealed to the basest motives of those whom it attempts to reach, setting cash above conscience in medical practice. It seems much more concerned with the maintenance of income than with the maintenance of satisfactory standards of treatment. True, it devotes considerable space in its pages to the business aspects of medical practice. Regardless, however, of the extent to which other scientific periodicals may have been derelict in their failure to discuss such matters as collection of bills, the credit standings of patients, the outfitting of an office, or legal methods of enforcing payment, "Medical Economics" also attacks the ideals and principles of organized medicine and attempts to create disruption in medical thought. Its effect is an insidious attempt to undermine the councils and committees that have made therapy scientific and thereby rendered precarious the livelihood of promoters of nostrums.

A more recent comer in this field is a periodical called "Modern Medicine," emanating from Minneapolis. This purports to be a medical periodical along the lines of *Time* magazine. It falls somewhat short of the *Time* standard both in the method of presentation of material

and in the quality of the material presented. Its advertising is for the most part of products that simply could not be accepted, yet it contains as an advisory board a list of leading names in the field of medicine, many of them officers of well established medical organizations. One wonders to what extent the services of these medical advisers are actually utilized. Are the names merely used in the promotion of the publication? There was a time when the names of vast numbers of doctors used to be put on periodicals to lend them status. Nowadays it is considered more reputable to refuse the use of one's name or to permit its use on an editorial board unless one is actually in some manner concerned with the policies of the periodical and the material it publishes.

A third class of periodical in the "throw-away" field is the one that purports to be a digest of medical literature, including either the abstracts or the condensations of medical articles. In the lay field such publications are sold by subscription and seem to serve a useful purpose.

For years manufacturers of proprietary medicine have been circulating house organs and other medical literature to physicians with the obvious intent of promoting interest in the drug field and particularly in the products which they manufactured. Such material was sent to the medical profession with the clear intent of selling goods. The new type of throw-away periodical has its intent concealed. It is thus not to be compared in its ethical status even with the type of house organ freely circulated by the proprietary medical interests. The mottoes of mankind for many centuries have warned against "something for nothing." "Beware the Greeks bearing gifts" goes back two thousand years.

THE EVALUATION OF SEROLOGIC PROCEDURES FOR THE DIAG- NOSIS OF SYPHILIS

A plan, now under way, to evaluate independently in the United States serologic procedures for the diagnosis of syphilis has much to commend it. Briefly, it is proposed to collect and transport comparable specimens of blood from approximately 1,000 donors to all serologists of this country who have described an original modification of a complement fixation or a flocculation test. Specimens sent to serologists most distant from the point of collection will be forwarded by air mail, and delivery to nearby serologists will be purposely delayed so that the delivery time to all participants will coincide. Great care will also be exercised in the selection of the donors. The first group will consist of syphilitic patients who have received varying amounts of anti-syphilitic treatment, and the third, or control group, of individuals who, on the basis of previous serologic and clinical examinations, are believed to be almost certainly not syphilitic. Consideration will also be given to the

influence of such diseases as tuberculosis, acute febrile diseases, leprosy, malignant growths and jaundice in the production of a positive serologic test. Specimens from such cases will be included in the third, or control, group if definite assurance can be obtained that the donor does not have syphilis.

An intelligent choice of patients in these several categories should serve as an accurate measure of specificity and sensitivity for all serologic tests for syphilis. Additional factors of importance in such an evaluation plan are the ease with which the procedures may be adopted by technicians generally, and their simplicity and rapidity of performance. No matter how effective a test may be in the hands of its originator, it cannot be regarded as reliable unless it can be applied with reasonable efficiency by other serologists and serologic technicians. Likewise, a test the technic of which is so simple and rapid that it can be performed daily is preferable to more complicated procedures of similar specificity and sensitivity.

The plan is fortunate in having the support of unprejudiced national organizations. It is sponsored by the United States Public Health Service, cooperating with the American Society of Clinical Pathologists. A committee consisting of five members—two clinical syphilologists of nation-wide reputation, two prominent members of the American Society of Clinical Pathologists, and an officer of the Public Health Service—will organize the project. The final reports from the participating serologists will also be interpreted by this committee on the basis of clinical information obtained from the individual donor.

Most American workers believe that the complement fixation test has been more highly developed in the United States than in any other part of the world. The efficiency of the American precipitation test was established by Kahn both at Copenhagen and at Montevideo. None of the American serologists who have described original modifications of the complement fixation test were represented at the other serologic conferences. The plan that is now proposed will permit a fair comparison of the best complement fixation and flocculation procedures in this country. It should not merely be of value in proving the efficacy of a given serologic procedure but should again focus the attention of the practicing physician on the importance of these tests in the diagnosis of syphilis. The information thus obtained should be made use of by the physician, the public health officer and others concerned with the important problem of the control of syphilis in assuring themselves that only the most specific and sensitive serologic procedures are employed.

The success of this plan is largely in the hands of the individual serologists. It is hoped that all such workers who have described an original modification of the complement fixation or the flocculation test will take part,

and that such an evaluation plan may be held in the future at intervals of from three to five years. Only in this way will an accurate picture of the progress of the serology of syphilis be available to the medical profession.

Current Comment

THYROIDECTOMY IN DIABETES MELLITUS

The influence of the thyroid gland in diabetes has been recognized since Dumontpallier reported a case of glycosuria with exophthalmic goiter in 1867. As the goiter improved under treatment so did the diabetes. Since that time there have been isolated reports of various associations of the thyroid gland and diabetes. So far as is known, however, the recent report of Wilder, Foster and Pemberton¹ is the first of complete resection of the thyroid gland in an uncomplicated case of severe diabetes. The patient was a man, aged 26, who had had severe diabetes of eleven years' duration. His basal metabolism was normal ($+5$ and $+2$ per cent). In spite of a rigidly restricted diet, about 45 units of insulin was required daily. Before the thyroidectomy he was placed on a diet of 2,300 calories, consisting of 103 Gm. of carbohydrate, 59 Gm. of protein and 183 Gm. of fat. An arbitrary dose of 10 units of insulin was given three times daily. The twenty-four hour excretion of dextrose in the urine on this regimen averaged 36 Gm. Following the operation, at which nearly all of the thyroid was removed, a small amount of thyroid tissue being left at the hilus of each lobe, progressive increase in sugar tolerance and progressive fall in basal metabolic rate were noted from about the tenth day. At dismissal, thirty days after the operation, the urine was practically sugar free with the patient on the previous diet with only 15 units of insulin daily. The basal metabolic rate was -29 per cent. Symptoms of myxedema appeared about sixty days after the operation. Twelve grains (0.8 Gm.) of desiccated thyroid was taken orally over a period of four days. The symptoms of myxedema disappeared promptly but the insulin requirement increased from 10 to 30 units. Two weeks after the desiccated thyroid was stopped the insulin requirement was back to 10 units, but thirty days later signs of myxedema recurred. This oscillation continued with the patient reporting dissatisfaction with the results six months later while taking from 8 to 10 units of insulin and one-tenth grain (0.006 Gm.) of desiccated thyroid daily. A year after the operation he wrote that he was comfortable, taking one-half grain (0.03 Gm.) of desiccated thyroid and from 14 to 16 units of insulin daily. This report serves as a good illustration of the substitution of one pathologic state for another. The interaction is self evident. With regard to the therapeutic procedure, few will be found to disagree with the patient and the authors that the improved sugar tolerance does not justify the production of a myxedematous state.

Association News

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD IN CHICAGO, SEPTEMBER 20 AND 21

The Board of Trustees met in Chicago at the headquarters office on September 20, and at the Palmer House on September 21 during the Annual Conference of Secretaries of Constituent State Medical Associations.

COUNCIL ON PHYSICAL THERAPY

The Council on Physical Therapy, which had been invited to meet with the Board, attended the Thursday morning session and took part in a lengthy discussion of the work to be undertaken by that body.

USE OF PERIODIC HEALTH EXAMINATION FORM BY NATIONAL COMMITTEE ON GIRLS AND BOYS CLUB WORK

Permission was granted to the National Committee on Boys and Girls Club Work to use a modified form of the Association's periodic examination blank.

CHAIRMAN OF LOCAL COMMITTEE ON ARRANGEMENTS

The nomination of Dr. W. J. Carrington to act as chairman of the Local Committee on Arrangements for the Atlantic City Session of the Association was confirmed by the Board.

APPOINTMENTS

The following appointments were made: Dr. Frank Hammond Krusen to membership on the Council on Physical Therapy, with a view to complying with the resolution adopted by the House of Delegates at the Cleveland session of the Association providing for additional physical therapists on that body. Dr. Lydia Roberts to the Committee on Foods, to succeed Dr. James S. McLester, who is now President-Elect of the Association. Dr. H. Douglas Singer, editor-in-chief of the *Archives of Neurology and Psychiatry* to succeed Dr. T. H. Weisenburg (deceased). Dr. William H. Park, New York, and Dr. George M. Piersol, Philadelphia, to succeed themselves as representatives of the American Medical Association to the American Association for the Advancement of Science. Dr. Ludvig Hektoen and Dr. Urban Maes to succeed themselves on the Advisory Committee of the Committee on Scientific Exhibit. A committee composed of Drs. C. B. Wright, Rock Sleyster and Austin A. Hayden to confer with a similar committee of the American Dental Association on matters of mutual interest.

APPROPRIATIONS

Appropriations were made to enable the Committee on Mental Health to carry out its plans for the current year, and for subsidized and section exhibits in the Scientific Exhibit for the Atlantic City session.

EXPRESSION OF APPRECIATION TO NATIONAL BROADCASTING COMPANY

The appreciation of the Board was expressed for the courtesy of the National Broadcasting Company in granting the Association a fifteen minute period every Tuesday afternoon from 4 to 4:15 over its chain.

REQUEST FOR EXHIBIT FOR DEPARTMENT OF MEDICINE AND HEALTH OF MUSEUM OF SCIENCE AND INDUSTRY

A request from the Museum of Science and Industry for the Association's exhibit at A Century of Progress after the close of that exposition was granted, with the understanding that the exhibit will be placed in the Department of Medicine and Health.

PHYSICIANS SERVING ON ADVISORY BOARDS OF MEDICAL PERIODICALS

The acceptance on the part of physicians of membership on advisory boards of medical periodicals in the publication of which they have no voice was deprecated by the Board.

ENTERTAINMENT OF BRITISH PHYSICIANS IN 1935

Plans were arranged for the entertainment of members of the British Medical Association who come to the United States

in August 1935 en route to the meeting of that Association in Australia.

MISCELLANEOUS BUSINESS

Various resolutions adopted by the House of Delegates were given consideration, and necessary steps were taken with a view to carrying out the provisions of those resolutions.

Numerous other matters were given attention and reports on many of these will be made later.

The Board adjourned, to meet in Chicago November 15 and 16.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be as follows:

October 25. What Is a Serum? W. W. Bauer, M.D.
November 1. The Common Drinking Cup, W. W. Bauer, M.D.
November 8. Your Child's Sleep, W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next three broadcasts will be as follows:

October 23. Reading About Health, W. W. Bauer, M.D.
October 30. Diphtheria Must Go, W. W. Bauer, M.D.
November 6. The Fight Against Appendicitis, W. W. Bauer, M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Naturopathic Initiative Measure.—A naturopathic initiative measure will be voted on by the electorate of Arizona, November 6. This measure proposes to create a board of naturopathic examiners to examine and license naturopaths, to exempt naturopaths from the basic science requirement, to license without examination naturopaths who have been practicing in Arizona for three years, to license without examination naturopaths who hold "certificates" from the American Naturopathic Association, Arizona District, to authorize naturopaths to practice in any hospital supported by public funds, and to confer on naturopathic licentiates the right to practice the healing art without express limitations.

The Indian Service Physicians.—The Indian office, Washington, D. C., has approved the recent organization of the Indian Service Medical Society at Winslow with the following officers: Drs. Hudspeeth E. Scoles, Tuba City, president; Marshall E. Burgess, Oraibi, vice president, and Le Roy Jones, Winslow, secretary. The area covered by the membership extends from the Consolidated Ute Agency with headquarters at Ignacio, Colo., through the Navajo country to Truxton Canyon Agency at Valentine, on the west. To date there are twenty members and six honorary members. The purposes of the society are to promote cooperation among service physicians and to enhance the value of their services to the government. All physicians and dentists of the U. S. Indian Service are eligible for membership. A meeting of the society was held at Fort Defiance, October 10.

CALIFORNIA

Another Veterans' Hospital Opened.—The new Veterans' Administration Facility in San Francisco has been opened. Dr. James G. Donnelly is manager of the institution, which has a capacity of 334 beds. A staff of ninety nurses and attendants has been assembled.

Infantile Paralysis Among Nurses.—The closing of the Orange County Hospital, Orange, October 4, to all except emergency cases was necessitated by an outbreak of infantile paralysis among the nurses. The normal nursing force numbers about forty. Five patients in the hospital have infantile paralysis, the *Chicago Tribune* reported.

Los Angeles County Given Health Award.—The American Public Health Association, at its recent annual meeting in Pasadena, presented to Dr. John L. Pomeroy, health officer of Los Angeles County, the Peter Ling Award. Each year the association presents the award to the county having the lowest infant mortality rate in the nation. For the fiscal year 1933-1934, there were thirty-eight infant deaths per thousand live births, newspapers reported.

Naturopath Placed on Probation.—Axel O. Lindstrom, a naturopath of San Francisco, was placed on probation for five years at a recent meeting of the California State Board of Medical Examiners, following a hearing of charges that he aided and abetted an unlicensed practitioner who operated the Gillberg Institute, 406 Sutter Street. At the same meeting of the board, the license of Will H. Coleman, naturopath, was revoked, on a charge of practicing beyond the limitation of his license.

Naturopathic Initiative.—A naturopathic initiative measure, to be voted on by the people of California, November 6, will, if adopted, create a public corporation to be known as the "Naturopathic Association of California." This corporation is to be vested with exclusive jurisdiction over naturopathy, conducting examinations and issuing licenses. Naturopathic licentiates will be given all the rights and privileges of any and all other practicing physicians of any class in the treatment of any and all diseases, injuries, deformities or other mental or physical conditions. The right to practice in all institutions supported wholly or in part by public funds will be accorded naturopaths.

DISTRICT OF COLUMBIA

University News.—Dr. Hans Lauber, professor of ophthalmology, University of Warsaw, Poland, addressed the faculty and students of George Washington University School of Medicine, October 2, on "Heredity, Particularly in Relation to the Eye."

Colonel Ashburn Appointed Hospital Superintendent.—Dr. Percy M. Ashburn, colonel, U. S. Army, retired, is now superintendent of Columbia Hospital for Women, Washington. Colonel Ashburn began his services with the army in 1898, and he was retired, Dec. 31, 1931. He is the author of "The Elements of Military Hygiene," 1909, and "History of the Medical Department of the United States Army," 1929.

GEORGIA

Appointments at University of Georgia.—New appointments to the full time faculty of the University of Georgia School of Medicine, Augusta, include the following:

Dr. Sam M. Brock, professor of surgery.
Dr. Evans B. Wood, assistant professor of gynecology and obstetrics.
William F. Hamilton, Ph.D., professor of physiology and pharmacology.
Everett S. Sanderson, Ph.D., professor of bacteriology and public health.
Fred A. Mettler, Ph.D., assistant professor of anatomy.
W. R. Brown, assistant professor of chemistry.
Robert A. Woodbury, Ph.D., assistant professor of physiology and pharmacology.
Robert B. Dienst, Ph.D., assistant professor of bacteriology and public health.

The new wing of the University Hospital, named for Milton Antony, who founded the school in 1828, was to have been completed about October 1. The building was made possible by a grant from the Public Works Administration and by funds contributed by the Alumni Association, the city of Augusta and the county of Richmond. It will have an outpatient department on the first floor and a contagious disease hospital on the second.

ILLINOIS

Society News.—At a special meeting of the Will-Grundy County Medical Society in Joliet, October 3, Drs. Joseph Colt Bloodgood, Baltimore, and Max Cutler, Chicago, were the speakers, on cancer. Dr. Philip Lewin, Chicago, addressed the society, October 10, on "Classification, Etiology and Treatment of Arthritis."—Dr. James H. Hutton, Chicago, addressed the DeWitt County Medical Society, October 4, on the endocrine aspects of essential hypertension.

Chicago

Dr. Leake to Lecture.—Dr. James P. Leake, senior surgeon, U. S. Public Health Service, Washington, D. C., will give an illustrated lecture before a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine at the Chicago Woman's Club, October 26. His subject will be "Poliomyelitis, with Special Reference to Epidemiology." Dr. Leake has been in California for several months studying the epidemic there.

Sir Harold Gillies Speaks at Northwestern.—The fourth annual Mayo Lecture in Surgery will be delivered by Sir Harold Gillies, London, at Thorne Hall, McKinlock Campus, Northwestern University School of Medicine, October 23. His subject will be "The Development and Scope of Plastic Surgery." Sir Harold is on the staffs of several hospitals, including St. Bartholomew's and St. Andrew's, London.

The Belfield Lecture.—Dr. Paul R. Cannon, professor of pathology, University of Chicago, will present the sixth annual William T. Belfield Lecture at the Palmer House, October 25, under the auspices of the Chicago Urological Society. His subject will be "Bacterial Localization." Preceding the lecture there will be a fellowship dinner at 6:30 p. m. in honor of Dr. Cannon, to which all members and guests of the society are invited. This lecture was established in 1929 in honor of Dr. Belfield, a founder of the Chicago Urological Society.

"The Common Cold."—The Chicago Medical Society will devote its meeting, October 24, to a symposium on the common cold, presented by the following physicians:

Russell L. Cecil, professor of clinical medicine, Cornell University Medical College, New York, Influenza and the Common Cold.
Frank Jirka, director, state department of health, Springfield, Field Studies of the Common Cold.
William V. Bauer, director, bureau of health and public instruction, American Medical Association, The Economic Cost of the Common Cold.
Walter H. Nadler, associate professor of medicine, Northwestern University School of Medicine, Treatment, Complications and Sequelae of the Common Cold.

The evening has been designated "General Practitioner's Night." Dr. Edward H. Ochsner will give a demonstration prior to the symposium on x-ray carcinoma of the hands.

Dr. Jordan Awarded Medal.—Edwin O. Jordan, Ph.D., formerly chairman of the department of hygiene and bacteriology, University of Chicago, was awarded the Sedgwick Memorial Medal for distinguished service in public health at the annual meeting of the American Public Health Association in Pasadena in September. Although he retired officially from the university in 1933, after forty-one years' service, Dr. Jordan has been offering graduate courses and has continued his research in the department of hygiene and bacteriology. He had been chairman of the department since it was set up in 1914, and professor since 1907. He is editor of the *Journal of Preventive Medicine* and joint editor of the *Journal of Infectious Diseases*. He is a former president of the Society of American Bacteriologists and the American Epidemiological Society. He is the author of many volumes on bacteriology and related subjects, and co-author of a biography of W. T. Sedgwick, for whom the medal is named.

INDIANA

Many Years in Practice.—A recent meeting of the Grant County Medical Society was devoted to honoring the following physicians who had been in practice forty years or longer: John C. Knight, Jonesboro; Leander H. Conley, Gas City; John F. Loomis, Marion; William A. Fankbouer, Marion; William S. Resoner, Swayzee; Nettie B. Powell, Marion; Edwin M. Trook, Marion, and Zed T. Hawkins, Fairmount.

Meeting of Anesthetists.—Twenty-eight physician-anesthetists, from all sections of the state, assembled for a dinner meeting at Purdue University, Lafayette, September 11, to establish contact between Purdue Research Foundation and the practicing specialists in anesthesia. Speakers included Dr. Franklin S. Crockett, Lafayette, who discussed the recent ruling of the state board of medical examiners that the administration of an anesthetic was in fact medical practice. A petition was signed, looking toward the organization of a section in anesthesia in the state association, according to the *Journal of the Indiana State Medical Association*.

Society News.—A symposium on rheumatic fever will be presented before the Indianapolis Medical Society, October 23, by Drs. Russell R. Hippensteel, George S. Bond and Horace M. Banks. Dr. Roy W. Scott, Cleveland, will address the society, October 30, on "Modern Aspects of the Problem of Vascular Disease." A symposium on foreign bodies in the lungs constituted the program of the society, October 2; Drs. Lyman T. Meiks, Cecil S. Wright and Delbert O. Kearby were the speakers.—Dr. Otis C. Higgins, Lebanon, discussed encephalitis before the Boone County Medical Society at Lebanon, October 2.—At a meeting of the Hendricks County Medical Society in Danville, September 28, Fredric R. Henshaw, D.D.S., dean, Indiana University School of Dentistry, spoke on the relation of medicine to dentistry.—The Porter County Medical Society was addressed at Valparaiso, September 25, by Dr. Sidney A. Portis, Chicago, on "The Medical Management of Gallbladder Disease."—The Delaware-Blackford County Medical Society was addressed in Muncie, September 18, by Dr. Henry E. Bibler, Muncie, on encephalitis.

IOWA

Society News.—Speakers before the Jackson County Medical Society, August 2, were Drs. Dean M. Lierle and Nathaniel G. Alcock, Iowa City, on "Otolaryngology from the Standpoint of the Practitioner" and "Resection Method in the Treatment of Diseases of the Prostate," respectively. Dr. Russell L. Cecil, New York, will speak before the Linn County Medical Society, October 25, on arthritis. Dr. Joseph B. DeLee, Chicago, addressed the society in Cedar Rapids, October 4, and showed motion pictures on forceps operations and episiotomy; Dr. James Stuart McQuiston, Cedar Rapids, presented a paper on "Functional Diseases and General Medicine."

KANSAS

Society News.—Dr. Clifford C. Nesselrode, Kansas City, addressed the Southeastern Kansas Medical Society in Chanute, September 13, on cancer. Dr. Kerwin Armand Fischer, Arkansas City, addressed the Cowley County Medical Society in Winfield, September 20, on "Injuries to the Navicular Bone," and Dr. Fred E. Torrance, Winfield, syphilis. Dr. Edward T. Gibson, Kansas City, Mo., addressed the Lyon County Medical Society at Emporia, September 4, on "Treatment of Head Injuries."

State Cancer Program.—Plans for an educational program against cancer were recently adopted by the Kansas Federation of Women's Clubs at a meeting addressed by Dr. Earle G. Brown, secretary of the state board of health and state chairman of the American Society for the Control of Cancer. Other speakers were J. Scott Walker, D.D.S., Chetopa, president of the state dental society, and Dr. Clifford C. Nesselrode, Kansas City, chairman of the cancer committee of the state medical society. According to the *Bulletin* of the American Society for the Control of Cancer, a three year health program emphasizing cancer control is anticipated.

KENTUCKY

Personal.—Dr. Jacob Leland Tanner, Albany, has been appointed health officer of Henderson County. Dr. Herman T. Carter, Gilbertsville, has been chosen health officer of a new health unit to be established in Metcalfe County. Dr. John G. South, Frankfort, has been named chief of the bureau of registration of the state board of health, it is reported.

Society News.—Dr. Derrick T. Vail Jr., Cincinnati, addressed the Louisville Eye and Ear Society, October 11, on "The Ophthalmologist Looks at Dacryocystorhinostomy." Dr. Oscar O. Miller addressed the Louisville Medico-Chirurgical Society, October 12, on silicosis. Dr. James Royden Peabody will speak, October 26, on "Diagnosis and Treatment of Brain Abscess of Otic Origin." Dr. Stephen C. McCoy will be the speaker at a meeting of the Louisville Urological Society, October 30, on "Renal Resection." Dr. William Barnett Owen addressed the Society of Physicians and Surgeons of Louisville, October 18, on osteomyelitis.

LOUISIANA

Personal.—Dr. Glenn J. Smith recently resigned as superintendent of the East Louisiana State Hospital at Jackson, a position he had held since 1929; he has been succeeded by Dr. John A. Thames, Natalbany. Dr. Walter W. Poinboeuf, Bastrop, has been appointed director of the St. Landry Parish Health Department, with headquarters at Opelousas.

Resolution Urges Health Unit Be Discontinued.—In a resolution adopted at a special session in Opelousas, August 29, the St. Landry Parish Medical Society declared itself opposed to the continued operation of the local health unit and asked that the old system of the appointment of a health officer be adopted. The resolution states that there have been numerous complaints against the encroachment of the health unit on the legitimate interests of the practicing physicians of the parish, and suggests that the appropriation to maintain the unit be discontinued.

Society News.—Dr. Rudolph H. Kampmeier, New Orleans, addressed the Second District Medical Society at Norco, September 16, on diagnosis and treatment of infections of the respiratory tract. At a meeting of the Concordia-Catahoula Bi-Parish Medical Society in Jonesville, September 6, Dr. Naum G. Nasif, Jonesville, discussed diathermy in the treatment of lobar pneumonia. The Orleans Parish Medical Society was addressed in New Orleans, October 8, by Henry T. Scott, Ph.D., Madison, director, biologic research, Wisconsin Alumni Research Foundation, on "Light and Its Application to the Irradiation of Foods."

MARYLAND

Personal.—Dr. Francis Dana Coman, Baltimore, sailed, August 22, for Honolulu en route to New Zealand to join the Antarctic expedition of Lincoln Ellsworth. Dr. Coman accompanied Rear Admiral Richard E. Byrd on his first expedition to the Antarctic.

Semiannual Meeting.—The Medical and Chirurgical Faculty of Maryland held its semiannual meeting at Point Lookout, October 11-12. Dr. Leonard B. Johnson, Morganza, president, St. Mary's County Medical Society, gave the address of welcome, and Dr. George O. Sharrett, Cumberland, president of the medical faculty, the response. The scientific session was given over to papers by Drs. Eugene L. Flippin on "Roentgen Findings in Primary Malignancy of the Lung"; Howard E. Ashbury, "Management of the Cancer Patient," and Sydney R. Miller, "Present Concepts of the Diagnosis and Therapy of Chronic Nephritis."

Society News.—The Baltimore City Medical Society was addressed, October 19, by Drs. Adolph Weinzirl on "The Diphtheria Prevention Campaign in Baltimore"; John T. King Jr., "Factors in the Etiology of Hypertension," and Harvey B. Stone and James C. Owings, "Living Grafts and Thyroid and Parathyroid Glands." Dr. Newton W. Hershner, Mechanicsburg, Pa., was elected president of the Cumberland Valley Medical Association at its thirty-second annual meeting in Hagerstown in September. Other officers elected are Drs. Henry C. Lawton, Camp Hill, Pa., and Julius E. Kempster, Chambersburg, Pa., vice presidents, and Drs. William A. Gordon, Hagerstown, and Percy D. Hoover, Waynesboro, Pa., secretary and treasurer, respectively.

MASSACHUSETTS

Committee on Research in Dental Medicine.—A committee on research in dental medicine comprising seven representatives of the faculty of arts and sciences and the medical and dental schools has been appointed at Harvard University. The committee has been given general supervision over research in the dental school. Its purposes will be to promote important dental research, act as a clearing house for research that is important to other fields, and to provide official contacts through which the dental school can readily get assistance for its research problems that overlap those of other departments. A grant from the Milton Fund has been given to the committee for work on its first problem, which will deal with the effects of nutrition on teeth and their supporting structures. Members of the new committee are Elmer P. Kohler, Ph.D., Abbott and James Lawrence professor of chemistry; Alfred C. Redfield, Ph.D., professor of physiology and director of the Biological Laboratories; Dr. Simeon B. Wolbach, Shattuck professor of pathologic anatomy, and consulting pathologist to the Cannon Commission of Harvard University; Dr. Walter B. Cannon, George Higginson professor of physiology; Percy R. Howe, S.D., Thomas Alexander Forsyth professor of dental science, and instructor in pathology, Harvard Medical School; Lawrence W. Baker, D.M.D., professor of orthodontia, and George P. Matthews, D.M.D., instructor in anatomy. Dr. Leroy M. S. Miner, dean of the dental school, will serve as a member ex officio of the committee.

MINNESOTA

Trudeau Celebration.—Dr. James Burns Amberson Jr., New York, was the guest speaker in the celebration of the Minnesota Trudeau Medical Society, October 6, to observe the eighty-sixth anniversary of the birth of Dr. Edward Livingston Trudeau. Dr. Trudeau was born, Oct. 5, 1848. Dr. Amberson's subject was "Estimation of the Healing Process in Pulmonary Tuberculosis and Its Importance in Treatment." The tribute to Dr. Trudeau was made by Dr. Walter J. Marcle, Minneapolis.

MISSISSIPPI

Society News.—At a meeting of the Issaquena-Sharkey-Warren Counties Medical Society in Vicksburg, September 11, speakers included Dr. George W. Gaines, Tallulah, La., on "Streptococcal Sore Throat." Dr. Edgar Burns, New Orleans, addressed the Pike County Medical Society, recently, on genito-urinary tuberculosis. Speakers before the Tri-County Medical Society at Monticello, September 11, were Drs. John W. Wilson, Monticello, on significance of adenitis; John R. Markette, Brookhaven, what vomiting may indicate, and Oscar N. Arrington, Brookhaven, hematuria. The next meeting of the society will be held in Brookhaven, December 10. A clinical pathologic conference on heart disease was a feature of the meeting of the Northeast Mississippi Thirteen

Counties Medical Society at Houlka, September 12; guest speakers were Drs. James S. McLester, President-Elect of the American Medical Association, and George S. Graham, Birmingham, Ala. Other speakers on the program were Drs. Theodore H. Rayburn, Pontotoc, on subphrenic abscess; William T. Pride, Memphis, Tenn., conduct of a normal labor case, and Douglas D. Baugh, Houston, recognition of common mental disorders.

Illegal Practitioners Investigated.—The Mississippi State Board of Health has provided the following news about certain illegal practitioners. Affidavits were made against "Dr. C. Hester," McCall Creek, July 9, for practicing medicine without a license. Investigation disclosed that he had obtained a copy of the license of Dr. Charles F. Hester from the records in the circuit clerk's office at Philadelphia and passed himself off as this physician. He filed this copy of the license with the circuit clerk at Meadville. It is reported that he pleaded guilty, paid his fine and court costs and was to have left the state; however, it was stated that he is still practicing. He had been arrested and charged with obtaining a narcotic license fraudulently. Dr. Charles F. Hester, now living in Amarillo, Texas, is the only physician with this name ever licensed to practice in Mississippi. He testified at the trial of the imposter "Dr." R. C. Watts, colored, was tried, July 10, at Anguilla, on a charge of practicing medicine without a license; he was convicted, the fine being suspended on condition that he would leave and stay out of the state. Richard Tigue, colored, was tried before a justice of the peace near Louisville, August 18, for practicing medicine without a license. He was charged with delivering a woman in labor. The attorney who pleaded his case endeavored to show that no fee was paid for the service. Tigue was convicted and fined \$200; the verdict was appealed to the circuit court of Winston County. Joe Hatton, colored, has been acting as a midwife for colored women in Jones County for several years. He pleaded guilty in his trial before a justice of the peace at Soso and was given a suspended fine of \$200 on condition that he refrain from this practice. Other investigations are being conducted in Coahoma, Hinds, Lafayette, Pearl River, Rankin, Tippah and Winston counties. The state board of health urges practicing physicians to cooperate with it in this campaign against illegal practitioners.

NEW JERSEY

Society News.—Drs. George T. Pack, New York, and Samuel M. Beale, Sandwich, Mass., addressed the Bergen County Medical Society, Hackensack, September 11, on "Recent Advances in Cancer Research" and "Small Doses of Insulin," respectively. Dr. Edward J. Donovan, New York, addressed the society, October 9, on "Abdominal Surgery in Children." —Dr. William D. Haggard, Nashville, Tenn., addressed the Atlantic County Medical Society, Atlantic City, October 12, on "The Delayed Operation for Appendicitis in Delayed Cases—An Analysis of 3,225 Operative Cases." —Dr. S. Bernard Wortis, New York, addressed the Hudson County Medical Society, Jersey City, October 2, on "Head Injuries—Treatment and Evaluation."

NEW YORK

Personal.—Dr. Henry R. O'Brien, Oberlin, Ohio, recently health commissioner of Lorain County, Ohio, has been appointed assistant district health officer on the staff of the New York State Department of Health. —Dr. William A. Howe, chief of the medical inspection bureau of the state education department, retired October 1, after being associated with the department since 1915. —Dr. Philip J. Raffe of the staff of the state department of health, has been appointed temporary district health officer with headquarters in Syracuse until a successor to the late Dr. Frederick W. Sears is selected by civil service examination. —Colleagues of Dr. Edward R. Baldwin, director of the Edward L. Trudeau Foundation, Saranac Lake, marked his seventieth birthday, September 8, by presenting him an armchair. Dr. James Woods Price made the presentation speech at a gathering at Dr. Baldwin's home in the evening, attended by about twenty-five physicians and others.

New York City

Society News.—Among speakers at a meeting of the Society for Experimental Biology and Medicine, October 17, were Drs. Irving Sherwood Wright, on "Treatment of Adult Scurvy with Crystalline Vitamin C (Ascorbic Acid)"; Alfred N. Richards, Ph.D., Benton B. Westfall, Ph.D., and Phyllis A. Bott, Philadelphia, on "Renal Excretion of Insulin, Creatinine and Xylose in Normal Dogs." —Dr. Mortimer N. Hyams gave an afternoon lecture before the Medical Society of the County of Queens, October 5, on "Sterilization of the Female by

Coagulation." —Dr. John L. Rice, health commissioner of New York, addressed a joint meeting of the Medical Society of the County of Queens and the Queensboro Tuberculosis and Health Association at Forest Hills, September 26, on "Municipal Control of Tuberculosis."

Hospital Planning Board Established.—Planning of hospital buildings under the jurisdiction of the city department of planning and construction set up by Dr. Sigismund S. Goldwater, hospital commissioner, October 11. Responsibility for critical examination of building plans will be vested in a board made up of the following: the medical superintendent of the department, a representative of the division of engineering, the head of the division of nursing and the head of the division of dietetics. In addition, the department's director of laboratories and director of roentgenology will be associate members, and the superintendent of the individual hospital affected in any case will be a member ex officio. In the future plans for hospitals will not be accepted until they have received the written approval of this board, it was said.

OHIO

State Medical Election.—Dr. Ralph R. Hendershott, Tiffin, was chosen president-elect of the Ohio State Medical Association at the annual session in Columbus, October 4-6. Dr. John A. Caldwell Jr., Cincinnati, became president. The 1935 meeting will be held in Cincinnati.

Anniversary of Library Association.—The fortieth anniversary of the founding of the Cleveland Library Association was celebrated at a dinner in honor of its charter members at the Allen Memorial Library Building, October 19. Dr. William E. Bruner gave a talk on the founding of the library and Dr. Howard T. Karsner, an appreciation of surviving charter members.

Third Graduate Course.—The Cleveland Academy of Medicine will present its third graduate course beginning October 26 and continuing weekly until March 22. The course this year is in the general field of obstetrics and gynecology. The first eight lectures will be as follows:

October 26, Physiology of the Female Genital Organs Including Endocrinology, Dr. Robert L. Faulkner
November 2, Functional Disorders of Menstruation, Dr. Gerald B. Hurd
November 9, Sterility, Dr. James L. Reycraft.
November 16, Diseases of the Ovary, Dr. Marion D. Douglass Jr.
November 23, Diseases of the Uterus, Dr. William D. Fullerton.
December 7, Carcinoma of the Cervix and Radium Treatment, Dr. Lawrence A. Pomeroy
December 14 and 21, Nonoperative Treatment of Gynecologic Conditions, Dr. William H. Weir.

OREGON

Cult Initiative Measure.—On November 6, the electorate of Oregon will vote on a proposed initiative measure to adopt a "healing arts amendment" to the constitution of the state. This constitutional amendment, if adopted, will abolish the requirements that all practitioners of the healing art shall demonstrate their fitness in anatomy, physiology, pathology, chemistry and hygiene before a nonsectarian, impartial board. It will confer on examining boards and schools of drugless healers the right to enlarge the scope of practice of drugless healers at will. It will permit injured employees to select any physician, including drugless healers, to treat their injuries. It will require all hospitals to admit any practitioner of the healing art, including drugless healers, selected by any injured or sick person to the hospital. It will deprive the legislature of Oregon of any further jurisdiction over the practice of the healing art in the state.

PENNSYLVANIA

Society News.—Dr. George W. Ramsey, Washington, addressed the Washington County Medical Society, October 10, on acute pancreatitis. —Dr. Harry Ryerson Decker, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, October 11, on treatment of pulmonary infection. —Dr. John P. Henry, Pittsburgh, gave a clinical demonstration of the injection treatment of varicose veins before the Cambria County Medical Society, Johnstown, October 11, and Dr. Bernard J. McCloskey, Johnstown, discussed "Treatment of Empyema by Aspiration." —Dr. Horace B. Anderson, Johnstown, addressed the Bedford County Medical Society, September 20, on heart failure. —Dr. Harold A. Miller, state director of emergency medical relief, Harrisburg, addressed the Delaware County Medical Society, October 11, on "The Present Social Order in Its Relation to Medical Care Given to the Indigent and the Necessity for Study of Alternate Methods with the Thought of Constructing a Program Agreeable to All."

Philadelphia

Society News.—Dr. Maurice N. Richter, New York, addressed the Pathological Society of Philadelphia, October 11, on "Experimental Aspects of Leukemia."—Speakers at a meeting of the Philadelphia Roentgen Ray Society, October 11, were Drs. Barton R. Young and William Edward Chamberlain, on "Hodgkin's Disease: A Clinical and Roentgenologic Review," and Wendell C. Hall, "Roentgenologic Significance of 'Milk of Calcium' Bile."—Dr. Alfred Gordon, among others, addressed the Philadelphia Psychiatric Society, October 12, on "Epilepsy and Arteriosclerosis."

Discussion of Hospital Problems.—The regular meeting of the Philadelphia County Medical Society, October 10, was devoted to discussion of hospital problems. E. H. Lewinski-Corwin, Ph.D., New York, discussed "The New York Hospital Situation"; Mr. Charles F. Neergaard, hospital consultant, New York, "The Hospital Situation with Special Reference to Philadelphia"; Dr. Harold A. Miller, state director of emergency medical relief, "Alternative Methods of Medical Functioning in Relation to the Indigent," and Mr. Louis I. Matthews, superintendent of St. Luke's and Children's Hospital, "Lay and Professional Relationships in Hospitals."

TENNESSEE

Flexner Lectures at Vanderbilt.—Prof. Erik Gunnar Nyström, professor of surgery at the University of Upsala, Sweden, will give the fourth series of the Abraham Flexner Lectures at Vanderbilt University School of Medicine, Nashville, in February and March, 1935.

Society News.—Dr. James R. Reinberger, Memphis, addressed the Hamilton County Medical Society, Chattanooga, September 27, on "Results in Repair of Relaxed Perineum at Time of Delivery."—Drs. Horace B. Cupp and Carroll H. Long, Johnson City, addressed the Washington County Medical Society, October 4, on "Backache: A Problem in Ex-Service Men" and "Diagnosis and Treatment of Endocrine Disorders in the Female," respectively.—Dr. C. C. Hacker was recently elected mayor of Elizabethton.—Dr. Hugh J. Morgan addressed the Nashville Academy of Medicine, October 2, on "Factors Conditioning the Transmission of Syphilis by Blood Transfusion."

District Meeting.—The third district of the Tennessee State Medical Association held a meeting in Chattanooga, September 28, with Dr. James S. McLester, Birmingham, Ala., President-Elect of the American Medical Association, as the guest of honor. Dr. McLester delivered an address on "Recent Advances in Our Knowledge of the Deficiency Diseases" at the scientific meeting and spoke at an evening banquet. Other speakers included Drs. Gilbert Madison Roberts, Chattanooga, on "Transurethral Prostatic Resection"; Robert P. Ball and Stanton S. Marchbanks, Chattanooga, "Roentgen Examination in Obstetrics" and William E. Van Order, Chattanooga, "Abdominal Pain in Children."

WASHINGTON

State Medical Election.—Dr. Nathan L. Thompson, Everett, was elected president of the Washington State Medical Association at the annual session in Corvallis, September 12. Dr. Curtis H. Thomson, Seattle, was reelected secretary. The 1935 meeting will be held in Everett.

GENERAL

International Radiologic Congress.—Dr. Arthur C. Christie, Washington, was elected president of the International Congress of Radiology at the recent session in Zurich, Switzerland, and it was decided to hold the next congress in the United States in 1937, possibly in Chicago. Dr. Benjamin H. Orndoff, Chicago, was elected general secretary.

Saunders Memorial Medal.—Recommendations for candidates for the 1935 Walter Burns Saunders Memorial Medal should be sent to the headquarters of the American Nurses' Association, 50 West Fifth Street, New York, before December 31. This medal is given for distinguished service in the cause of nursing. Rules governing eligibility may be obtained from the association.

Society News.—The annual conference of the National Society for the Prevention of Blindness will be held in New York, December 6-8. Subjects selected for discussion will be causes of blindness, sight saving classes, prevention of eye accidents, and prevention of prenatal accidents that may cause blindness. Dr. Edward Jackson, Denver, will make the principal address, on "A Wide Basis for Blindness Prevention."—Dr. John Shelton Horsley, Richmond, Va., was elected

president of the American Society for the Study of Neoplastic Diseases at its meeting in Washington, September 6-8, succeeding Dr. Max Cutler, Chicago. Dr. Charles F. Geschickter, Baltimore, was named vice president and Dr. Eugene R. Whitmore, Washington, D. C., secretary.

Death Rates in Large Cities.—An analysis of the vital statistics of twenty-eight large cities made by the New York City Department of Health shows a general death rate for 1933 of 10.95 per thousand of population. Washington, D. C., had the highest rate (15.89) and Milwaukee, the lowest (8.23). Among the five largest cities Chicago had the lowest infant mortality rate (.49); the lowest rates in the group were for Seattle, Portland, Ore., and Oakland, Calif., each 38 per thousand live births. The highest rates were for Buffalo, N. Y., and Columbus, Ohio, each 69. The highest rates for some important causes of death were as follows: cancer, Boston, 176 per hundred thousand; pulmonary tuberculosis, Washington, D. C., 103.2; diabetes, Jersey City, N. J., 36.6; typhoid, Washington, 3.6; diphtheria, Louisville, Ky., 10.4; suicides, San Francisco, 37.6; homicides, Houston, Texas, 26.1; automobile accidents, Los Angeles, 36.2. Lowest rates for the same causes were: cancer, Houston, 70.3; pulmonary tuberculosis, Minneapolis, 14.7; diabetes, Houston, 10.3; typhoid, Portland, Ore., none; diphtheria, Seattle and Rochester, N. Y., none; suicide, Jersey City, 8.3; homicide, Milwaukee, 2.2; automobile accidents, Rochester, N. Y., 13.8.

World Prevalence of Smallpox.—Figures assembled by the Health Section of the League of Nations showing the distribution of smallpox throughout the world during the past two years indicate a noticeable decline in the United States. The total number of cases reported in 1933 was 6,233, as against 49,000, 30,000 and 11,000 during the previous three years. A study of the regional distribution shows that the disease is rare in the Northeastern states, relatively high in the Central and Southern states and highest in the Far West. Elsewhere in North America smallpox is also on the decline but still causes several thousand deaths each year in Mexico. Portugal and the Soviet Union are the only important smallpox foci in Europe; in both countries it appears to be of the serious type, according to the report, whereas in many countries the mortality is extremely low. In 1933 Egypt had the most serious epidemic of smallpox in Africa, with 5,697 cases and nearly 1,000 deaths; it has definitely declined during 1934. The number of cases rose in the Belgian Congo from 1,241 in 1931 to 3,410 in 1933. In Asia the most important focus is British India, for which provisional figures showed 250,000 cases in 1933. In the ports of China, where there was an epidemic in the winter of 1932-1933, the disease remained endemic, with a slight rise in Shanghai in the early months of this year. Japan has also had an increase after being comparatively free for several years.

CANADA

Personal.—Dr. James A. Faulkner, Belleville, has been appointed minister of health for Ontario, succeeding Dr. John M. Robb. Dr. John M. Uhrich, Regina, has been appointed minister of public health for Saskatchewan.—Dr. Alberic Marin was recently elected president and Dr. Paul H. Poirier, secretary, of the Montreal Dermatological Society.

Society News.—At the annual meeting of the British Columbia Medical Association in Kamloops, September 17-18, the speakers included: Drs. James C. Masson, Rochester, Minn., on "Malignancy of the Large Bowel" and "Use of Living Sutures in the More Difficult Abdominal Herniae"; William P. Murphy, Boston, "Therapeutic Effects of Intramuscular Injections of Liver Extract," and Francis M. Pottinger, Monrovia, Calif., "Role of the General Practitioner in Diagnosis of Tuberculosis."

Bar Sale of Dinitrophenol.—Changes in the Food and Drugs Act to correct discrepancies between it and the Proprietary or Patent Medicine Act were enacted by the recent federal parliament and will go into effect Jan. 1, 1935, according to the *Canadian Medical Association Journal*. The principal change was to insert in the Food and Drugs Act a list of nearly forty diseases for which remedies cannot be sold. The journal points out that since obesity is one of the conditions listed, the sale of dinitrophenol would appear to be barred.

CORRECTION

A Defense of Suprapubic Prostatectomy.—In a letter on prostatectomy by Dr. E. L. Keyes (*THE JOURNAL*, October 6, p. 1086, column 1, bottom of page), the statement "172 suprapubic cystotomies" should be "172 suprapubic prostatectomies."

Sept. 22, 1934.

The International Sanitary Control of Aerial Navigation

The government has published the report of the International Sanitary Convention for Aerial Navigation, which has been signed by most of the important countries of the world. If the regulations adopted are properly carried out, the risk of conveyance of disease from one country to another should be minimized. Each country undertakes to provide at its aerodromes a sanitary organization adapted to the current needs of prophylaxis, which as a minimum will consist of the attendance of a physician at such times as may be necessary for the medical examinations contemplated by the convention. It rests with each country to take into account the risk of infectious disease to which its territory may be exposed and to decide whether to establish sanitary aerodromes, which will have an organized medical service with one medical officer and one or more sanitary inspectors, who will not necessarily be in constant attendance. The sanitary aerodrome will have (1) equipment for taking and dispatching suspected material for examination in a laboratory, if such examination cannot be made on the spot; (2) facilities for the isolation and care of the sick, for the isolation of contacts separately from the sick, and for the carrying out of disinfection and deratization. In the journey log of the aircraft the following must be entered: 1. Any facts relevant to public health which have arisen in the course of the voyage. 2. Any sanitary measures undergone by the aircraft before departure or at places of call, in application of the present convention. 3. Information concerning the appearance in the country of departure of the following infectious diseases: plague, cholera, yellow fever, typhus and smallpox. If any of these diseases appear in a noninfected country, the aerodrome authorities shall enter the information in the journey log of any craft leaving it during a period of fifteen days from the receipt of the information. The medical officer of the aerodrome has the right of sanitary inspection of the passengers and crew, and on his advice the embarkation of persons with symptoms of infectious diseases may be prohibited. Aircrafts in flight are forbidden to let fall matter capable of causing an outbreak of infectious disease.

REGULATIONS APPLICABLE TO CERTAIN INFECTIOUS DISEASES

Plague, cholera, yellow fever, typhus and smallpox are subject to special measures. For purposes of the convention the period of incubation of plague is reckoned as six days, of cholera five days, of yellow fever six days, of typhus twelve days, and of smallpox fourteen days. The measures to be adopted on the departure of an aircraft from a local area infected by plague, cholera, typhus or smallpox are (1) thorough cleansing of the aircraft, (2) medical inspection of passengers and crew, (3) exclusion of any person showing symptoms of these diseases as well as of persons in such close relation with the sick as to be liable to transmit these diseases, (4) inspection of personal effects, which shall be accepted only if in a reasonable state of cleanliness, (5) in case of plague deratization, if there is any reason to suspect the presence of rats on board. On arrival from such infected areas the aircraft may be required to land at a prescribed sanitary or authorized aerodrome and the movements of the passengers and crew may be restricted. If there is on board a recognized or suspected case of plague the following measures are applicable: (1) immediate disembarkation of the sick, (2) surveillance of contacts and sus-

pects for a period not exceeding six days, (3) disinfection and disinsectization of personal effects, and (4) deratization. For a case of cholera the measures are similar except that the period of surveillance is five days and the drinking water may be disinfected and emptied. For typhus the measures are similar except for delousing and surveillance for twelve days after this. For smallpox the special measures are vaccination and surveillance for a period not exceeding fourteen days of those on board. In regions in which yellow fever has occurred or is endemic aerodromes must be at an adequate distance from the nearest inhabited center, provided with a water supply protected against mosquitoes and with mosquito-proof dwellings for the aircraft crews and for the accommodation of passengers. The aircraft and cargo must be inspected to see that they do not contain mosquitoes and, if necessary, disinfected. Passengers and crew may be put under surveillance for six days from exposure to infection.

New Regulations for the Dusty Industries

New and more stringent regulations have been made by the government for the dusty industries, which include the refractories, sandstone, pottery and asbestos. Those seeking employment in these industries must be examined by a member of the medical board. Their employment will not be allowed if their physique does not satisfy the following requirements: 1. The chest must be at least of average development and the respiratory passages free from obstruction. 2. There must be no sign of disease of the lungs or heart. 3. There must be no tuberculosis in any region.

PARIS

(From Our Regular Correspondent)

Sept. 12, 1934.

A New Vaccine Against Plague

Important research on vaccination against plague has been carried out in Madagascar, in the Institut Pasteur de Tananarive, by Girard and Robic, the results of which were recently reported by Professor Mesnil to the Academy of Medicine. The vaccines against plague at present in use are prepared from cultures of killed bacilli, which confer an immunity of only a few weeks duration. The soldiers who are vaccinated before they leave the capital lose the greater part of their immunity by the time they reach their destination in the colonies and it is often necessary to repeat the vaccinations, which sometimes give rise to unpleasant anaphylactic reactions. Girard and Robic have prepared a new vaccine, with living bacilli derived from strains that have been attenuated by many successive cultures, according to the method that Calmette employed in the preparation of the BCG vaccine against tuberculosis. With this new vaccine they have vaccinated 15,000 persons among the population of the high plateaus of Madagascar, where both the pulmonary and the bubonic form of plague is rather frequent, with a high mortality. From March 1 to April 15, an average of 150 new cases per week was recorded, only a third of which were of the bubonic type. No untoward incidents were observed following the vaccinations. No vaccinated persons have contracted the plague as yet, although many were living in infected surroundings. It would seem that, owing to these measures, the epidemic will be eradicated soon.

Tuberculosis in the Army

The detection of tuberculosis among the young men who are enlisted by conscription for the army is a matter of great importance. The law has decided that any soldier who is declared by the army physicians to be in perfect health on his arrival at the barracks, and who later becomes tuberculous, is assumed to have contracted the disease during his military service, which fact not only entitles him to an immediate discharge from the army but also to a pension for the remainder of his life. This constitutes a heavy burden on the budget.

Hence the army physicians are urged to exercise great care in the examination of recruits, each of whom must undergo two examinations. The first examination is given at the time the young conscript presents himself for the first time to the registration officers the day before his enlistment. This examination is a hasty and summary proceeding, being public and extending over only a few minutes. It enables the examiners to eliminate only those who are unacceptable at first sight, by reason of undersize, insufficient chest development, deformities, albuminuria, diabetes and the like. Following this examination, conscripts are accepted only provisionally and assigned to their respective units. Thereupon the chief physician of the regiment proceeds with an individual detailed examination. He is allowed a period of three months in which to complete his examinations, and he may, if he deems it necessary, send any recruit for a consultation with specialists in the military hospitals of the nearest large city. It often requires shrewdness to detect the simulators. Formerly it was common for some to simulate deafness, excessive myopia or dysentery in order to be relieved of military service. Since the enactment of the new law the reverse is true. Now the simulators seek to conceal any disease with which they are affected in order not to reveal it until after two examinations have been completed, so that their disease may be declared to be a consequence of military service and give them the right to a pension. The physicians take great precautions to detect all fraudulent practices, most of which are well known to them. Considerable improvement has been brought about by the ruling that all conscripts are to be subjected to a thorough radioscopic examination before they are definitely assigned to their unit. Médecin général Rouvillois, in collaboration with Messieurs Christian and Liégeois, reported recently to the Academy of Medicine the first results obtained following the introduction of radioscopic examinations in the army. The idea was first proposed by Médecins généraux Rieux and Sieur, but it took time to procure the technical equipment and the requisite personnel. The results secured confirm the importance of the introduction of this means of investigation. Out of a total of 115,150 recruits examined, 1,093 eliminations were made and final or temporary discharges were granted, representing an average of 9.4 to the thousand, which included 143 persons in whom open tuberculosis was diagnosed. These observations are interesting because they have to do mostly with recruits who had already been accepted at the first examination. The number of cases of tuberculosis detected by systematic radioscopic examination constitutes about one third of the cases detected at the first examination. Following this address, Professor Sergent emphasized the value of this innovation and expressed the hope that the same methods would be applied before persons are allowed to enter any collective group: high schools, universities or even factories. Mr. Béclere took occasion to stress the need of distinguishing types of tuberculosis in an active state from old lesions long since cured.

Noise in the Cities

The steady increase of the external noises today in all large cities has finally begun to attract the attention of hygienists. A crusade against noise has been organized by many municipalities. Almost everywhere one encounters the indifference of the public authorities and the selfishness of the persons responsible for the noises. Some have gone so far as to deny the existence of the nervous disorders produced by noise and to say that noise disturbs only neuropaths and persons who are already ill—who would do well to move into the country. In opposition to such views, Dr. Segard has published a clinical study on what he terms the "Syndrome of Persons Suffering from the Noise Evil." He distinguishes the effects of continuous noises from unexpected noises, which produce a nervous shock, the repetition of which is positively harmful. To the

latter class belong noises of gasoline motors, particularly motorcycles and airplanes, loud speakers and phonographs, and the like. A few years ago it was common to compare the irritability of city dwellers to the calmness of villagers. Noises cause nervous disorders. They provoke disturbances of sleep, digestive disorders, irregularity of the pulse and an increase in blood pressure. Dr. Segard stated that the special commission on the noise evil, with headquarters in New York, has estimated that in mental workers this syndrome observed in persons subjected to noises reduces by 20 per cent their working capacity. It is the duty of the municipalities and the responsible authorities to pass regulations controlling the use of automobile horns, locomotive whistles, factory sirens, loud speakers, phonographs and radio sets and to prevent unnecessary noises of vehicles, advise and prescribe the construction of buildings of sound-proof materials, and impose effective penalties for violations of the specifications. It has been proposed that persons troubled by noises at night should put pledgets of absorbent cotton or wax in the ears to reduce the transmission of sound. But such measures are only partially effective and are not without danger. From time to time, persons who are affected by the noises of the city should spend a short period in the country. It would be a good thing if the authorities of certain small cities would make more widely known the measures they have adopted to prevent noise. They would not fail to attract many persons from the large cities who are seeking a quiet place in which to spend their vacation.

Heredity and Diseases of the Blood Vessels and Kidneys

Professor Weitz addressed recently the Berlin Medical Society on "Hereditability of Diseases of the Heart, the Blood Vessels and the Kidneys." Congenital cardiac defects are relatively more frequent in certain families and are concordant in dizygotic twins. In one family, pronounced cyanosis could be followed through four generations in seven persons. Numerous necropsy reports refer to similar congenital cardiac defects in siblings. Frequently not only a general predisposition to malformations of the heart are inherited but also even the predisposition to certain definite malformations. The hereditary course may apparently be dominant and recessive.

In acquired cardiac defects, external factors play an essential part. In enzygotic twins, acquired cardiac defects are frequently found to be discordant. A hereditary predisposition must be assumed. Since researches on twins show that a tendency to sore throat is decidedly hereditary, this is doubtless, in many cases, the explanation for the familial aspects of heart defects after endocarditis.

Constitutional cardiac disease is found chiefly in vasoneurotic, infantile and asthenic subjects and in persons with disturbances of the internal secretions. Researches on families and on twins show that vasomotor disturbances, a tendency to extrasystoles and to paroxysmal tachycardia, drop heart and pendulous heart are traceable to hereditary factors.

It has been observed that there are families in which there is a high incidence of the consequences of hypertonia; for example, cerebral hemorrhages. The parents of young hypertonic patients die at an early age from heart disease and cerebral hemorrhage. The hereditary course is in this case dominant.

Alcoholism, mental excitement, immoderate physical exertion and the ingestion of animal protein constitute external factors that serve as precipitating causes in the manifestation of the predisposition. In this connection, interest attaches to investigations on monks. In contrast to monks using a mixed diet, hypertension was seldom found in monks subsisting on a vege-

tarian diet. Arteriosclerosis shows a certain connection with hypertension, and in a heredobiologic study they cannot be entirely separated. Also cerebral arteriosclerosis and angina pectoris have been found to have a familial incidence.

Weitz reports having observed several instances of hypertension in parents and children. Concordant behavior in enzygotic twins and familial occurrence prove the hereditary nature of thrombo-angiitis obliterans. With respect to varices, family trees have been studied that point unequivocally to a dominant hereditary transmission of the predisposition. In enzygotic twins, varices that occurred were always concordant.

Of the renal diseases one must examine, for three reasons, the heritability of glomerulonephritis: an increased incidence among siblings following diseases that seldom give rise to nephritis; increased incidence of scarlatinal nephritis in some siblings; increased incidence of nephritis in the family in general.

The cystic kidney in the new-born is probably a recessive hereditary disorder. Cystic kidney in adults, which usually appears beyond the forties in a much more harmful form, seems to have a dominant hereditary course. Since in many cases a cystic kidney is associated with a grave malformation, sterilization is to be considered.

Treatment of Spasm of the Pylorus

In recent years, hypertrophic stenosis of the pylorus in infants has frequently been operated on in accordance with a procedure introduced by Professor Ramstedt of Münster. In 1929 Ramstedt sent a questionnaire to about sixty children's clinics and hospitals for infants to secure information concerning the results of this method. This questionnaire revealed that, during the ten-year period from 1919 to 1928, 1,842 cases of pylorospasm had been treated in the institutions solicited for information. The mortality ranged around 18 per cent, internists reporting a mortality of 16 per cent, while that of cases coming to operation was 22.5 per cent. A recent inquiry of the same nature and extent covers 2,432 cases, with a general mortality of 10.7 per cent, internists reporting a mortality of 9 per cent, while that of cases coming to operation was 14.4 per cent. Thus there has been not only a marked increase in the number of cases but also a gratifying reduction of the mortality in this dangerous disorder. Today this disorder is better diagnosed—more frequently in its beginnings, so that treatment can be begun earlier. Whether the splitting of the hypertrophic pylorus muscle, which Ramstedt recommended, has proved its worth is doubtful, for there is as yet no general agreement as to the indications for operation. The success of surgical treatment makes a better showing if the results of certain clinics that applied only operative methods or only internal methods are compared. In two such series of cases the mortality among 958 infants receiving internal treatment was 10 per cent, and among 1,609 infants receiving surgical treatment, only 8.5 per cent. In the series of cases coming to operation, fifteen pediatricians and surgeons who are advocates of the early operation had an average mortality of only 4 per cent. The children's clinic in Düsseldorf has made a careful comparison. Up to 1928, conservative methods were used exclusively. From 1919 to 1928 the mortality in ninety-two cases was 18.4 per cent; later (1927-1933), when surgical procedures exclusively were employed, the mortality in a series of 110 cases was only 3.6 per cent (four deaths). It would appear that the question has been decided in favor of the operative method. The children treated by operation get well much more rapidly, and they are much less likely to contract intercurrent diseases and infection.

Professor Hertel, surgeon at the University of Münster, expressed himself thus: Up to the present the Ramstedt operation has been performed in twelve cases, in all of which a cure was effected. The age of the patients on the day of the

operation ranged between 16 days and 4 months, the average being about 7 weeks. The average duration of treatment was thirty-five days, although in a few instances a child could be dismissed at the end of eleven days. The increase in weight of the infants during this period was about 840 Gm. The vomiting ceased usually immediately after the operation; in some cases it continued several days, being evidently connected with the elimination of the reflex disturbances.

Professor Vogt, ordinarius in pediatrics at the same university, said that the question of choice of method cannot be decided by the scrutiny of statistics, for there is no reason to feel assured that the comparison of the successes is being based on truly comparable cases. Stenoses of the pylorus are sometimes produced by other causes than a simple hyperplasia of the musculature; for example, by changes in the position of the duodenum, with kinking. Experience does not justify the assumption of definite periods within which internal treatment must show good results. In some cases it may take a week and in other cases two weeks or longer before there is a definite turn for the better. Hence progress can be expected only from further research on the dynamics of the various clinical manifestations. In any event, the endeavor to get along with internal treatment without operation is justified primarily by the observations that show the clinical symptoms may disappear permanently in spite of the fact that hypertrophy of the pylorus remains.

Hence, in mild cases, as Ramstedt admits, internal treatment must be tried first, and the pediatrician should select the cases for operation and also determine the time for the operation. That, moreover, the effects of pyloromyotomy are not always immediate is due to the facts that sometimes the muscular hypertrophy along the pyloric ring, which is pushed forward toward the duodenum like a cervix, is especially well developed and that precisely this portion is often difficult to reach with the knife or cannot be divided without danger of opening the duodenum. Such an accident must be avoided without fail.

Diabetes in Jews

Professor H. Strauss, director of the department of internal medicine of the Jewish Hospital in Berlin, has been able to show by mortality statistics that diabetes is of frequent occurrence in Jews. Women are somewhat more frequently affected than men (280:271). The researches on heredity revealed that hereditary influences played a part in 20.6 per cent of the cases in women and 29.7 of the cases in men. The hereditary influence manifests itself usually in a recessive form. A large majority of the patients were merchants. That wealth exerts a decided influence could not be demonstrated. More than three fourths of the cases were moderate or mild. In a large number of cases, only diabetes innocuus was involved. In 20 per cent of the cases the duration of the disorder extended over eight years or more. Polydipsia as a beginning symptom was demonstrated in men in 46 per cent and in women in 40 per cent of the cases. Pruritus was an associated disorder in 27.5 per cent of the women. Furunculosis was more frequent in men than in women. Gangrene of the extremities was found in 7 per cent of the men and in 5 per cent of the women. In the opinion of Strauss, the real frequency of diabetes in the Jews is due to hereditary influences and to increased lability of the vegetative nervous system.

The Health of School Children

In 1925 Professor Czerny and Professor Keller, pediatricians of Berlin, reached the conclusion that the damage to the development and the health of children caused by the war period was less than was expected. The economic crisis in 1930 and the increasing unemployment have awakened renewed interest in the matter. Also the League of Nations has studied the question of "Economic Crises in Relation to Public Health." Examination of school children in later years did not reveal

harmful late effects of war conditions. A change occurred, however, in 1933, for health conditions among the youth took a turn for the worse last year. Many different types of infectious disease appeared in the districts controlled by school physicians—often in an unusual form. Of decisive significance, as Professor Keller points out, was the condition discovered in the children who entered school for the first time in February 1934. The entrance examination revealed the wretched bodily condition of the children born in the years 1927 and 1928. Many of these children gave evidence of very poor nutrition and a poor constitution. A normal set of teeth was rare, and it was evident that they lacked adequate resistance toward disease. Hence special welfare measures must be applied to these children, and they must receive supplementary food allowances for the first few months of school life. Physicians engaged in social work should determine the extent of this impaired condition of health among school children and endeavor to remedy conditions as promptly as circumstances will permit.

Personal

Prof. Kurt Schneider of Munich has received a call to the chair of psychiatry, as the successor of Prof. W. Weygandt (retired), in Hamburg.

Prof. Erich Hoffmann, ordinarius for dermatology at the University of Bonn, has been relieved of his official duties and has been appointed an outside member of the Georg Speyer-Haus in Frankfurt-on-Main.

Prof. S. J. Thannhauser, ordinarius for internal medicine in Freiburg-im-Breisgau, has been retired by reason of the new legislation pertaining to officials. Professor Bohnenkamp of Giessen has been appointed his successor and will serve also as director of the University Medical Clinic.

Professor Jacobsthal of Hamburg has been called to the University of Guatemala as professor and director of the Bacteriologic Institute.

Dr. H. Löhr, superintendent of the Bethel Hospital, near Bielefeld, has been appointed ordinarius for internal medicine at the University of Kiel, to succeed Professor Schittenhelm, who has been called to the University of Munich.

Professor Nonnenbruch of Prague has declined a call to the chair of internal medicine in Hamburg, as the successor of Prof. L. Brauer, retired.

Prof. Otfried Müller, director of the University Medical Clinic in Tübingen, has been relieved of his official duties because of illness.

Dr. R. Fetscher, extraordinary professor of eugenics and biology as pertaining to heredity, at the Dresden Polytechnicum, has been retired by reason of the new legislation.

Prof. F. Dessauer, radiologist and ordinarius for medical physics at the University of Frankfurt-on-Main has been retired by reason of the new legislation.

Professor Broemser of Heidelberg has accepted a call to the chair of physiology at the University of Munich.

Prof. Heinrich Braun, formerly director of the infirmary in Zwickau, has died at the age of 71. Braun performed meritorious service in the development of local anesthesia and is the author of a textbook on this subject.

Prof. P. Mühlens of Hamburg has been appointed director of the Hamburg Institut für Schiffs- und Tropenkrankheiten, in which he had been serving as department director. He has likewise become ordinarius in tropical medicine at the University of Hamburg.

Prof. Dr. Paul Krause, ordinarius in internal medicine in Münster (Westphalia), is a suicide at the age of 62.

Prof. Dr. Heinrich Eymer of Heidelberg has accepted a call to the chair of gynecology at the University of Munich, as the successor of Geheimrat Professor Doederlein, retired.

Prof. Dr. Gustav Aschaffenburg, psychiatrist and ordinarius of Köln, has been relieved of his official duties.

RIO DE JANEIRO

(From Our Regular Correspondent)

Aug. 15, 1934.

Malignant Diphtheria

Drs. Jose M. da Rocha, pediatrician of the Hospital São Sebastião, and Clarindo Rabello, intern of the hospital, reported before the Society of Pediatrics a case of malignant diphtheria in a child, aged 9 years, which died in four days. Necropsy revealed punctiform hemorrhages in the skin and mucosae and hemorrhages in the lungs, kidneys, heart, peritoneum and stomach. They had injected 100,000 units of anti-diphtheritic serum, of which 20,000 was given intravenously. Cases of hemorrhagic malignant diphtheria are rare in Rio de Janeiro but they have become more frequent lately. The authors reviewed the various theories on the causes of malignant diphtheria: bacterial association, virulence, toxicity of the germs and toxins, and constitutional factors. They came to the conclusion that the factor of greatest importance is a constitutional predisposition to hemorrhages.

Roentgenkymography of Aortic Aneurysms

Dr. J. M. Cabello Campos, roentgenologist of the Sanitary Service of Santa Casa and of the Institute of Hygiene of São Paulo, presented to the Society of Medicine and Surgery some work on roentgenkymography. He enumerated the difficulties encountered in practice in diagnosing tumors of the mediastinum, particularly aneurysms, in which the relations of the tumor mass to the artery and its movements are valuable signs. After giving an outline of the technic employed and a description of the apparatus in use, he reported in detail the kymographic curves of four cases of aneurysm. Roentgenkymography is indispensable in the differential diagnosis of tumors of the mediastinum.

Arteriosclerosis in Vienna

Addressing recently the Vienna Medical Society, Dr. Fellner reported his observations on 12,000 patients with arteriosclerosis. His research considered the degree and the dissemination of sclerosis in the aorta, the coronary vessels, the vessels of the brain, and the remaining large arteries. It was found that, as a rule, women contract the disease later than men and present a milder type. Not until the age of 70 is reached are the curves for the two sexes approximately the same. One finds, however, fatty degeneration of the vessels more frequently in women. Calcification begins with the arteries of the brain after the age of 35, and from 10 to 15 per cent of the 70-80 age group give distinct evidence of this condition. The heart vessels are calcified in about 50 per cent of the persons belonging to the age groups above 60. A difference between the calcification of the aorta and the remaining vessels is seen only in inveterate smokers. Thirty per cent of the latter give distinct evidence of calcification of the peripheral vessels. The aorta and the heart vessels are more frequently calcified in persons of stocky build than in persons of a more athletic type; the latter, however, often present sclerotic heart vessels. Obese persons show a tendency to fatty degeneration of the vessels—obese women particularly. Sclerosis appears earlier and more frequently in Jews than in the average population. In the rural population, the disease develops later and in a milder degree. Social factors appear to play a part. The well-to-do classes are inclined to live a sedentary life and doubtless ingest more toxins in their diet; hence arteriosclerosis appears earlier in this class. The same thing is true of mental workers. In the latter class, however, not the brain but the aorta is attacked

earlier and more severely. Severe physical labor that is combined with considerable movement does not predispose a person to early sclerosis; but if the severe labor is done in a standing position with little movement (porters, laundresses), arteriosclerosis develops early. Alcohol addicts are no more predisposed to arteriosclerosis than are abstainers. Excessive use of tobacco, however, plays havoc with the blood vessels. Tuberculosis has no effect on the blood vessels, whereas syphilis produces grave changes, particularly in the ascending aorta. Rheumatism and carcinoma appear to have no influence on the vessel walls, although diabetes is frequently associated with early and severe arteriosclerosis. Gallstones and liver disorders frequently produce fatty degeneration of the vessels.

The Population of Vienna

On March 22, 1934, a census of Austria was taken, the preliminary results of which have been published. The population of Vienna is given as 1,874,618, which is a loss of 142,000 as compared with 1914. The total number of living births for 1913 was 12,137, and the total number of deaths was 23,472. In 1914 there were more than 26,000 births, which shows a decline of more than 50 per cent, over against 22,000 deaths. The excess of deaths over births, amounting in 1933 to 11,335, was counterbalanced by immigration. The total number of immigrants was 155,587, over against an emigration of 122,443, so that, in spite of the declining birth rate, the population had increased by 21,809. For the first quarter of 1934 the number of living births was 3,368; the number of deaths, 6,642; the number of immigrants, 35,426, and the number of emigrants, 30,019, so that the net increase in population for the first quarter of this year was 2,133.

The statistics for the Jews of Vienna are interesting. In 1914, and also in 1934, the Jews constituted about 10 per cent of the total population (200,000 and 178,000 respectively). The decline in the birth rate among the Jews (60 per cent) is possibly even greater than among the non-Jewish population, but the mortality is somewhat lower. There were no Jewish immigrants, and the emigration was small, although the last two years have shown an increase. An evident fact, however, is the constant distinct decrease in the Jewish portion of the population since 1920. From a total of 218,000 in 1918, the Jewish population has dropped to 178,000, signifying a loss of 40,000, or almost 20 per cent of the maximum.

A Study of Abortion

Professor Zacherl and Dr. Richter of the Innsbruck Geburtshilfliches Universitäts-Institut reported to the Austrian public health service on their research on the sequels of abortion. All statistical reports reveal a marked increase of abortion, since the war, among all civilized nations. It was found that the immediate damage resulting from abortion, such as death and inflammatory processes, is of less significance, on the whole, than the late results affecting the health of the woman and her fertility. The damage due to abortion may be considered under three heads: hemorrhages, infections and anatomic injuries. The speakers reported the results of their observations in a series of 2,000 gravidas in Innsbruck. The majority of the women presented after abortion various disorders of genital origin. Menstruation was much disturbed in more than 50 per cent, while amenorrhea was a frequent symptom. In a large number of cases, sterility was later demonstrable; likewise, anatomic changes in the genitalia were observed in many cases. Later births, and even pregnancies, are more likely to show complications than in women who have never had an abortion. Placenta praevia is especially frequent; likewise, weak labor pains are common, and prolongation and disturbance of the after-birth period. Death of the fetus before the end of term, habitual miscarriage and febrile births are relatively more fre-

quent in such women. Both speakers expressed the view that a large part of the late injuries following interruption of pregnancy are due to errors of technic. They recommend, therefore, a very conservative operative method in abortion and conservative after-treatment—methods that take careful account of the physiologic conditions. A common error of technic is the too radical removal of the uterine mucosa. The resulting inadequate regeneration produces a functional inferiority of the mucosa, with the aforementioned consequences, and also leukorrhea, chronic inflammations, disturbance of nidation of the ovum, and the frequently observed secretory, hormone disturbances.

Conflict Between the Vienna Faculty of Medicine and American Students

A controversy that threatened to destroy the friendly relations between the Vienna Faculty of Medicine and the medical students from America studying in Vienna was settled at the last moment by the intervention of the American ambassador to Austria and the Austrian ministry of public instruction. The controversy arose over the selection of courses of study designed for foreigners, which are largely attended by Americans. The society of American medical students bearing the name "American Medical Association of Vienna" has functioned satisfactorily for about thirty years. The society established, some years ago, its own committee for the selection of the courses to be given by English-speaking Vienna professors. It goes without saying that, in the selection of these courses, the wishes of the Americans, who were in the majority, received the chief consideration. The Vienna Faculty of Medicine has also its committee to decide what courses shall be given in the German language. For various reasons the attendance on these courses has been, in recent months, much reduced. In order to improve the attendance on its own courses, the committee of the Faculty of Medicine attempted to deprive the American Medical Association of Vienna of the right to organize its own (English) courses. Doubtless, certain political factors played a part in the controversy; for, in the Faculty of Medicine, there was evidence of influence traceable to the national-socialists. There seemed to be a movement to allow certain physicians the privilege of holding medical courses in English, but, at the same time, an endeavor was made to withhold this source of income from Jews.

In other words, the committee on courses of the Faculty of Medicine desired to furnish the association not only the courses but also the lecturers, without giving much consideration to the wishes of the students themselves. The proposal was rejected by the American physicians as being untenable, and they even went so far as to threaten to leave Vienna in a body if they were to be denied the privilege of selecting their own courses. In spite of this, the Faculty of Medicine, under the influence of political agitators, refused to yield. Thereupon the president of the association entered into correspondence with the universities of Prague and Budapest, which expressed a willingness to meet the requirements of the foreign physicians, in order to induce them to move to their city. The American ambassador in Vienna was informed of the situation, and he took up the matter with the ministry of public instruction. At last a way had been found to effect a solution of the difficulty. The ministry of public instruction issued an order that the selection of courses for the American physicians be continued to be made as in the past. By the events in July, which took the form of a Nazi revolt, the disturbing agitators in the Faculty of Medicine were eliminated, so that it appears likely that the differences between the Faculty of Medicine and the foreign medical society of Vienna will soon be settled and that the medical school of Vienna will retain its age-old position as a center for medical education.

Marriages

JUNIUS HAZEL McLEOD, Fayetteville, N. C., to Miss Waverly Gwynne Thomas of Smithfield, Va., August 5.

LINVILLE MURRELL HALLORAN, Beckley, W. Va., to Miss Frances Louise Williams of Lexington, Va., August 31.

ROBERT LUCIEN McCOLLUM, Flushing, N. Y., to Miss Virginia Muir of St. Albans, September 21.

MALACHI WILSON SLOAN JR., Berrysburg, Pa., to Miss Ellen Kathryn Wisler of Norristown, August 11.

FREDERICK EARL McLENDON, Athens, Ga., to Miss Bennie Venetta Bell of Nashville, Tenn., June 27.

RAYMOND L. CLATERBAUGH to Miss Louise H. Scruggs, both of Clifton Forge, Va., September 8.

JAMES F. CASTO, Topeka, Kan., to Miss Lorane Carder of Lawrence at Wellsview, September 9.

OSCAR ADOLPH KAER, Winston-Salem, N. C., to Miss Helen Elizabeth Seifert, September 24.

ENNETT A. DOLES, Havre, Mont., to Miss Claremae Vielleux of Fort Benton, September 29.

OSCAR LEE HITE, Richmond, Va., to Miss Inez De Jarnette of South Boston, September 22.

EDWARD CHARLES MAEDER, Minneapolis, to Miss Irene Kangas of St. Paul, July 24.

JAY McLEAN, New York, to Miss Georgia Alpin of Fayetteville, N. C., June 5.

FRANCIS W. BRIGGS to Mrs. Agnes Lamey, both of Havre, Mont., recently.

Deaths

Curran Pope of Louisville, Ky.; University of Louisville School of Medicine, 1889; member of the House of Delegates of the American Medical Association in 1912; past president of what is now known as the American Congress of Physical Therapy and the Ohio Valley Medical Association; member of the American Psychiatric Association and the Kentucky Board of Charities and Corrections; lecturer on pathology, bacteriology and microscopy, Hospital College of Medicine, 1891-1894; professor of neurology and psychiatry, Louisville College of Medicine, 1895-1899; adjunct professor of neurology, psychiatry and physical therapy, Kentucky School of Medicine, 1902-1908, and professor of physical therapy at his alma mater, 1909-1910; consulting neurologist and psychiatrist to St. Anthony's Hospital; medical director of a hospital bearing his name; author of "Practical Hydrotherapy"; aged 67; was found dead, September 21, of a self inflicted bullet wound.

Arthur Percival Procter, Vancouver, B. C.; Canada; Manitoba Medical College, Winnipeg, 1896; for twenty-two years registrar of the College of Physicians and Surgeons of British Columbia; for twenty-five years chief medical officer of the Canadian Pacific Railway for the British Columbia division; for seventeen years district medical officer department of pensions and national health, Shaughnessy Military Hospital; aged 67; died, August 20, of a gunshot wound.

Guy Edmund Manning, San Francisco; Hahnemann Medical College and Hospital of Philadelphia, 1890; at one time librarian, professor of materia medica, physiology and chemistry; Hahnemann Medical College of the Pacific; for many years member of the city board of health; health commissioner of San Francisco, 1907-1921; director of the Hahnemann Hospital, 1910-1918; aged 67; died, September 1, of cerebral thrombosis.

Edward Ernest Maxey, Aberdeen, Wash.; College of Physicians and Surgeons of Chicago, 1891; member of the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; served during the World War; past president and secretary of the Idaho State Medical Society; on the staffs of St. Joseph's and Aberdeen General hospitals; aged 67; died, August 31, of coronary occlusion.

Fellows Davis Jr., New York; Columbia University College of Physicians and Surgeons, New York, 1899; served during the World War; formerly on the staff of the New York Nursery and Child's Hospital; governor of the American Hospital, Neuilly, France; aged 62; died, September 5, at his summer home in St. James, L. I., of adenocarcinoma of the prostate.

Clarence Ruter Dufour, Washington, D. C.; Howard University School of Medicine, Washington, 1889; Georgetown University School of Medicine, 1890; member of the Medical Society of Virginia; formerly emeritus professor of clinical ophthalmology, Georgetown University School of Medicine; aged 71; died, September 11.

Richard Charles Weithas of Brooklyn; George Washington University Medical School, Washington, D. C., 1909; member of the American Urological Association; fellow of the American College of Surgeons; urologist to the Bushwick and Coney Island hospitals; aged 51; died suddenly, September 27, of heart disease.

John Milton Garrett of Fort Dodge, Iowa; Marion-Sims College of Medicine, St. Louis, 1892; Bellevue Hospital Medical College, 1896; past president and secretary of the Webster County Medical Society; on the staffs of the Lutheran and St. Joseph Mercy hospitals; aged 65; died suddenly, August 18, of heart disease.

Edward Montraville Swift of Perth Amboy, N. J.; Howard University School of Medicine, Washington, D. C., 1927; on the staff of the Perth Amboy General Hospital; aged 47; died, September 9, in the Mount Sinai Hospital, New York, of malignant hypertension, urcemia and heart disease.

Jacob H. Mitnick, Baltimore; Baltimore Medical College, 1890; member of the Medical and Chirurgical Faculty of Maryland; veteran of the Spanish-American and World wars; aged 76; died, September 22, of arteriosclerosis, diabetes mellitus and coronary thrombosis.

Samuel Pilgrim Gerhard of Philadelphia; Medico-Chirurgical College of Philadelphia, 1891; Jefferson Medical College of Philadelphia, 1893; formerly lecturer on medicine, Temple University School of Medicine; aged 67; died, September 8, of heart disease.

Cornelius DeWeese of Washington, D. C.; Jefferson Medical College of Philadelphia, 1895; member of the American Psychiatric Association; medical director of the Laurel Sanitarium, Laurel, Md.; aged 59; died suddenly, September 15, of cerebral hemorrhage.

James Arthur Kirk, Danville, Ill.; Hospital College of Medicine, Louisville, Ky., 1904; served during the World War; aged 53; on the staff of the Veterans' Administration Facility, where he died, September 3, of Hodgkin's disease and chronic pulmonary tuberculosis.

George Enos Burdick, Hines, Ill.; University of the City of New York Medical Department, 1888; served during the World War; on the staff of the Veterans' Administration Facility; aged 69; died suddenly, September 24, in Glen Ellyn, of coronary occlusion.

Marvin Whitfield Glasgow, Fairfield, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; aged 56; on the staff of the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company, where he died, September 20, of heart disease.

Antoine Paul Cartier, St. Hyacinthe, Que., Canada; School of Medicine and Surgery of Montreal, Que., 1872; formerly conservative member of the Quebec Legislative Assembly for the County of St. Hyacinthe; aged 85; died, July 10.

William N. Gilmore of East Liverpool, Ohio; Western Reserve University Medical Department, Cleveland, 1882; on the staff of the East Liverpool City Hospital; aged 76; died, August 29, of cerebral hemorrhage and arteriosclerosis.

Louis Nels Andersen of Inglewood, Calif.; College of Physicians and Surgeons, Medical Department Kansas City (Kan.) University, 1896; served during the World War; aged 70; died suddenly, September 6, of heart disease.

John Alva Longmore of Brooklyn; University of Michigan Medical School, Ann Arbor, 1900; formerly lecturer in medicine and chief of the clinic, Long Island College Hospital; aged 59; died, September 13, of heart disease.

Francis Bernard Conway, Boston; Tufts College Medical School, Boston, 1903; member of the Massachusetts Medical Society; aged 64; died, September 10, in the City Hospital, of coronary thrombosis and bronchopneumonia.

John Philip Dougherty of Sioux City, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1904; aged 59; died, August 18, following an operation for gallstones.

Belmont De Forest Bogart, New York; Columbia University College of Physicians and Surgeons, New York, 1896; aged 62; died, September 8, in the Hospital for Ruptured and Crippled, of hypertensive heart disease.

Bernard M. Turbow, East Chicago, Ind.; Chicago College of Medicine and Surgery, 1913; member of the Indiana State Medical Association; aged 48; died, October 2, at his home in Indiana Harbor, of coronary thrombosis.

Caesar A. Queirolo, Oakland, Calif.; Université de Genève Faculté de Médecine, Genève, Switzerland, 1897; aged 65; died, July 18, in the Providence Hospital, of carcinoma of the pleura with abdominal metastasis.

John Rogers Parry ♂ Woodsfield, Ohio; Medical College of Ohio, Cincinnati, 1878; formerly secretary of the Monroe County Medical Society; aged 79; died, August 29, of chronic myocarditis and arteriosclerosis.

Frank Lydston Newman, Detroit; Detroit College of Medicine, 1887; formerly emeritus professor of pharmacology and therapeutics at his alma mater; aged 74; died, August 23, of uremia and chronic nephritis.

Archibald Williamson, Richmond Heights, Mo.; Beaumont Hospital Medical College, St. Louis, 1889; aged 68; died, July 25, in the Evangelical Deaconess Home and Hospital, St. Louis, of carcinoma of the pancreas.

John Harrison Wedig ♂ Wood River, Ill.; Chicago College of Medicine and Surgery, 1910; served during the World War; aged 49; died, September 7, in St. Joseph's Hospital, Alton, of sarcoma of the lung.

Oscar Beesley Dunn, Ironton, Ohio; Miami Medical College, Cincinnati, 1878; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 84; died, September 11, of myocarditis.

Jesse Bell Porter, Fort Myers, Fla.; Northwestern University Medical School, Chicago, 1903; aged 62; died, August 1, in a hospital at Miami, of bronchopneumonia following bilateral herniotomy.

Stanislaus A. Kulick ♂ Detroit; Michigan College of Medicine and Surgery, Detroit, 1896; aged 59; died suddenly, September 5, at his summer home in Fair Haven, Mich., of cerebral hemorrhage.

Horace Greely Pangle, Russellville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1898; aged 61; died, September 6, in a hospital at Greenville, of diabetes mellitus and heart disease.

Henry Burton Parrish, Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1904; served during the World War; aged 55; died, September 23, in the Protestant Hospital.

Jefferson Woolsey, Karnes City, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; served during the World War; aged 64; died, July 26, of cerebral hemorrhage.

Joseph Edward Pelletier, Worcester, Mass.; School of Medicine and Surgery of Montreal, Que., 1903; aged 58; died, August 7, of arteriosclerosis, coronary sclerosis and auricular fibrillation.

Llewellyn C. Kellogg ♂ Loma Linda, Calif.; College of Medical Evangelists, Los Angeles, 1922; professor of anatomy at his alma mater; aged 58; died, September 1, of coronary occlusion.

Clement Emerson Sayers, Hawthorn, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; member of the Medical Society of the State of Pennsylvania; aged 66; died in June.

William Bidwell Page, Denver; University of Michigan Homeopathic Medical School, Ann Arbor, 1883; aged 77; died, September 2, of arteriosclerosis, coronary sclerosis and myocarditis.

Milton S. Gray, Phoenix, Ariz.; Ensworth Medical College, St. Joseph, Mo., 1896; member of the Missouri State Medical Association; aged 64; died, September 8, of heart disease.

Nolan Ray Currie, Jackson, Miss.; Birmingham (Ala.) Medical College, 1909; member of the Mississippi State Medical Association; aged 51; died, September 4, of heart disease.

George William Flynn, St. Louis; St. Louis University School of Medicine, 1910; member of the Missouri State Medical Association; aged 48; died, August 23, of heart disease.

Marie McGarvey Peake, Blair, Neb.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1900; aged 68; died, August 26, of polyneuritis and inanition.

Dale L. Walker, St. Clairsville, Ohio; Jefferson Medical College of Philadelphia, 1885; aged 73; died, September 8, in Columbus, of cerebral hemorrhage and arteriosclerosis.

Alwin Meigs Guittard, Cabanatuan, P. I.; Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1885; aged 74; died, July 14.

John Andrew Podsedly, Cleveland; St. Louis University School of Medicine, 1926; aged 34; died, August 9, in the Cleveland Clinic Hospital, of a pontile tumor.

George Oliver Gernon, Ste. Geneviève de Pierrefonds, Que., Canada; University of Bishop College Faculty of Medicine, Montreal, 1879; aged 80; died, July 1.

Jacob Kurnik, Brooklyn; Long Island College Hospital, Brooklyn, 1914; aged 46; died, August 26, in the Worrell Hospital, Rochester, Minn., of pemphigus.

Harry Lee Bell ♂ Knox, Ind.; Chicago College of Medicine and Surgery, 1908; served during the World War; aged 56; died, August 7, of acute myocarditis.

Timothy Charles Weber, West Salem, Ill.; Barnes Medical College, St. Louis, 1897; served during the World War; aged 64; died, August 28, of tuberculosis.

Aaron P. Baldwin, Tyler, Texas; Louisville (Ky.) Medical College, 1883; aged 76; died, July 10, of hepatitis, cholecystitis, myocarditis and chronic nephritis.

Julius H. Krueger, Chicago; Hahnemann Medical College and Hospital, Chicago, 1887; aged 88; died, September 25, of cerebral hemorrhage and arteriosclerosis.

Ida Leonora Schell ♂ Milwaukee; Northwestern University Woman's Medical School, Chicago, 1900; aged 71; died, September 21, of cerebral hemorrhage.

Albert M. Phillips, Eulogy, Miss.; University of Tennessee Medical Department, Nashville, 1887; aged 69; died, August 30, of cerebral hemorrhage.

Henry Jakob Strauch, Donora, Pa.; Jefferson Medical College of Philadelphia, 1928; aged 42; died, September 8, in the *Morro Castle* disaster.

James Patrick Coll, Jersey City, N. J.; Jefferson Medical College of Philadelphia, 1904; aged 51; died, September 8, in the *Morro Castle* disaster.

Charles Bloodgood, Grand Rapids, Mich.; Rush Medical College, Chicago, 1881; aged 81; died, September 7, of a self inflicted bullet wound.

Walton Worthey Shoemaker, Handley, Texas; Medical College of Alabama, Mobile, 1892; aged 77; died, July 26, in a hospital at Fort Worth.

William Erastus Wells, Tampa, Fla.; University of Louisville (Ky.) School of Medicine, 1901; aged 58; died, July 15, of dilatation of the heart.

James E. G. Simmons, Boyd, Texas; Atlanta (Ga.) Medical College, 1888; served during the World War; aged 74; died, July 26, of senility.

Albert James Storm, Collingdale, Pa.; Medico-Chirurgical College of Philadelphia, 1915; served during the World War; aged 46; died, July 14.

George Wilson Bass, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1890; aged 71; died, August 23, of arthritis.

Samuel Sal Murnick, Chicago; Loyola University School of Medicine, Chicago, 1922; aged 40; died, September 16, of organic heart disease.

Felix-Jasper Bray, Parsons, Tenn.; Vanderbilt University School of Medicine, Nashville, 1878; aged 80; died, August 29, of prostatitis.

Walter Gustavus Rundle, Lincoln, Neb.; Rush Medical College, Chicago, 1906; aged 58; died, September 10, of cerebral hemorrhage.

James M. Amiss, Silver Lake, Ind.; Medical College of Indiana, Indianapolis, 1880; aged 82; died, September 6, of hemiplegia.

Frank Songer, Hillsboro, Ind.; Medical College of Indiana, Indianapolis, 1891; aged 68; died, September 23, of chronic nephritis.

Walter Myers Gill, Dormont, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1888; aged 69; died, July 12.

Ralph Moore Peters, Minneapolis; Rush Medical College, Chicago, 1894; aged 62; died, August 12, of coronary thrombosis.

Eleanor Stallard Dailey, Omaha; Woman's Hospital Medical College, Chicago, 1878; aged 80; died, June 26.

Richard Gantz, Terre Haute, Ind. (licensed in Indiana in 1897); aged 89; died, September 7, of pneumonia.

Correspondence

THE INTRAVENOUS DRIP

To the Editor:—There appears to be some controversy as to priority in the use of the intravenous drip. I have been intensely interested in intravenous therapy during the past thirty years.

Dr. Rudolph Matas read a paper on "Continued Intravenous Drip" at a meeting of the American Surgical Association held at Rochester, Minn., in 1923, which was published in the transactions of the association for that year and in the *Annals of Surgery* (79:643 [May] 1924). In that paper he reported cases in which he applied the method as far back as April 1913 and even before that date. It was my pleasure to observe the use of the continuous intravenous drip under Dr. Matas's service while visiting the Touro Infirmary and Charity Hospitals, New Orleans, in January 1914. It has been in current use in these institutions since 1923, where it is usually designated as the "Matas drip."

Dr. G. A. Hendon of Louisville, Ky., has published a number of papers on the same procedure, under the title of "venoclysis." In a paper which he read at a meeting of the Southern Surgical Association in 1929 (*Transactions* 42:288, 1929) he says: "On May 12, 1924, I first employed the method," and again, "in June 1924, as a result of a paper on the continuous intravenous drip by Dr. Rudolph Matas, read before the American Surgical Association in June 1923. The paper was published in the *Annals of Surgery* for May 1924."

This acknowledgment from Dr. Hendon himself should suffice to settle the question of priority so far as he is concerned. The only difference is in the name "venoclysis," which he applied to the continued intravenous drip. This has been severely criticized by Cutting and others as a philologic barbarism, because it is a hybrid of Latin and Greek. Matas frequently referred to "phleboclysis" long before Hendon thought of "venoclysis," but even though "phleboclysis" is not so objectionable to philologic purists, it does not convey the notion of the continuance and duration of the procedure. The Greek "phleps" and "klysis" mean, literally, no more than a flushing out or washing of the vein, which is not strictly applicable to any intravenous injection. Although I am not so meticulous about words, I do believe that whoever attempts neologism, especially in scientific matters, should be, at heart, consistent and respectful of philologic rules.

In the *Louisville Courier Journal* of March 2, 1933, Hendon apparently claims to be the originator of the continued intravenous drip. Despite his admission that the practice of "venoclysis," as he calls it, was suggested to him by Matas's paper of 1924, his claim would appear somewhat belated.

In Germany, Friedmann of Langersdreer is recognized as the originator of the method, which he described for the first time at the meeting of Rhenira and Westphalian surgeons at Düsseldorf, Feb. 16, 1913. He then used salt solution for continuous instillation in the veins, from eight to twenty-three hours, reinforcing it with epinephrine, digitalis, and other drugs. This is an important historical event, because there has been some talk recently in Germany of celebrating the twenty-first anniversary of Friedmann's valuable innovation.

I believe there is no question that Friedmann is the first to have introduced the continued drip in Germany, just as I am confident that Matas was the first to use and publish a report of his experience with it, independently, in this country, without knowledge of Friedmann's work.

The records of Matas (as shown in his paper of 1924) go back to April 1913, therefore antedating the first publication of Friedmann's work in the *Zentralblatt für Chirurgie*, Dec. 6, 1913.

The first report ever made on intravenous infusion at the Charity Hospital of New Orleans, from June 1889 to June 1891, was published by Matas. This covered every case in which intravenous infusions had been resorted to in that institution during that period. The report appeared in two issues of the *New Orleans Medical and Surgical Journal* 19:1-22, 81-33, 1891. For this reason it is easy to understand that with this background of experience the value of the continued drip should have gradually suggested itself.

As to Cutting and his paper on the "Place of Phleboclysis in Surgery," which appeared in the *New Orleans Medical and Surgical Journal* for July 1933, it has nothing to suggest any discussion of history or questions of priority. It is a good review of the actual status of the question, with special stress on some debated new features, which had developed from 1923 to 1932, but there was no pretense at original discovery on the fundamentals.

W. FOREST DUTTON, M.D., Amarillo, Texas.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

HYPERSENSITIVITY

To the Editor:—I had severe asthma in my teens. It completely subsided after a cautery of what was said to be a hypertrophied inferior turbinal. I have not recently been altogether free from trouble. I have put it down to a reflex nasal cause, as cauterization of the nose relieves me for a while. My nasal mucosa too is extraordinarily sensitive to dust, chill and so on. I have noticed that it registers by immediate flow of secretion and sneezing on the slightest exposure to cold of any part of my body on a cold night. On a recent occasion the rhinologist had considerable difficulty in cocaineizing my nose, as I sneezed out every cocaine plug he put in prior to cauterization. Recently I had occasion to take a dose of antitetanic serum after a minor accident. As I had taken antitetanic serum two years before, I anticipated trouble because of my asthmatic history. Desensitization was started with a drop of undiluted serum. It raised a wheal and was followed by a few urticarial patches. Two more intradermal instillations of a drop each gave similar patches confined to the ipsilateral arm. Next day I had a frightful, widespread eruption of urticarial patches all over the body, not easily amenable to injections of epinephrine, intravenous calcium gluconate, dextrose, spirit of ammonia and ephedrine by mouth and saline purgatives. The urticaria subsided slowly in the course of the day. My blood showed no eosinophilia. I have since taken graded doses of antitetanic serum up to 1 cc. after testing with drop doses of diluted serum. All the doses gave local reactions in the shape of more than usual pain and hot swelling for two days. I should be obliged to you for information on (1) whether it is possible to desensitize my nose against the extraordinary sensitiveness to cold and (2) whether my "desensitization" against serum will be permanent. If not, is there any method of permanent desensitization? Please omit name and address.

M.D., India.

ANSWER.—The inquirer has hyperesthetic rhinitis and asthma, both probably of allergic origin. The early onset of the asthma, the associated rhinitis and the sensitiveness to horse serum are the prominent factors that speak for an allergic cause. The repeated temporary relief of the asthma following the use of the cautery in the nose does not justify the stamping of the asthma as reflex. Cauterization of the tonsils, tonsillectomy, a nasal operation, an appendectomy, a herniotomy or any procedure that traumatizes tissue or produces a hemorrhage may result in temporary relief of any allergic manifestation. This is due to the nonspecific effect of the absorbed organic matter.

Physical allergy to cold does exist as a primary phenomenon without concomitant allergy to chemical substances such as foods, pollens and animal danders. It must be recognized, however, that physical factors usually operate as secondary causes. Thus, perhaps the majority of instances of hyperesthetic rhinitis have attacks precipitated by physical (heat or cold), chemical (vapors, fumes), mechanical (inorganic dust), infections and neurogenic factors. And yet in most of these cases an underlying chemical allergy is present, which, if removed, will no longer be influenced by the secondary causes.

1. Whether a secondary or a primary factor, it is possible to gain a tolerance to cold. One method consists of taking daily baths, beginning with a temperature well above the point at which symptoms are usually produced and diminishing it by about 1 degree Fahrenheit every two or three days. After

a fairly low temperature is reached, tolerance may be maintained by daily cold baths. Another plan that may be pursued consists of a hot bath or exposure to a therapeutic lamp followed by a rub down with ice, followed again by exposure to heat.

2. Desensitization against horse serum in a sensitive individual to a degree that will allow him to take the usual amount of therapeutic or prophylactic serum is extremely difficult and almost impossible. Whatever "desensitization" or hyposensitization is accomplished is not permanent. The rapid method of attempting to gain a tolerance to horse serum in the space of a few hours is to be condemned not only for its lack of success but because of its great danger. It is important in this connection to differentiate between the naturally horse-sensitive individual and the one who has acquired sensitiveness to serum by a previous injection. In the latter type the degree of sensitiveness is usually much milder than in the first. If there is a history of asthma or rhinitis when the individual is around horses he may be, but is not necessarily, sensitive to horse serum. It is particularly in the latter type that serious and fatal reactions occur from the administration of horse serum.

It is perfectly possible that horse dander may play a part in the causation of the inquirer's asthma and rhinitis. Such dander could have its origin in the horsehair of mattresses or furniture and in the dust of the street, boulevards and parks, in which horse manure, mixed with horsehair, is used frequently for fertilizing and protective purposes. A more detailed discussion of the problem of horse dander and horse serum may be found in S. M. Feinberg's *Allergy in General Practice* (Philadelphia, Lea & Febiger, 1934, pp. 72, 152 and 154).

If the inquirer has not already done so he should test himself with various allergens, including horse dander, and, if he is found sensitive to the latter, treatment with extracts of horse dander would probably be advisable.

APPENDICITIS OR PYELITIS WITH OTITIS MEDIA

To the Editor:—About three weeks ago I was called to see a girl, aged 6 years, who complained of severe pain over McBurney's point. There was distinct rigidity over the rectus muscle, a temperature of 103 F. by rectum and a differential count of 84 per cent polymorphonuclears with a total count of 17,500 white cells. A surgeon confirmed the diagnosis of acute appendicitis and recommended operative intervention. The parents hesitated and requested me to call in a medical man. By the time the latter arrived the temperature had dropped over 2 points, pain had subsided to a great extent and the patient evidently felt quite better. A diagnosis of pyelitis was made by the physician; when urine examination was made, pus cells were found in the urine. The temperature kept going down and the abdominal pain kept subsiding, when suddenly the patient began to complain of severe earache and within thirty-six hours the drum had to be lanced, relieving a great amount of pus. Since then the patient has been kept in bed. She complains of pain soon after eating and still shows pus in the urine, while the temperature ranges between 99 by rectum in the morning and 101 in the evening. The ear still discharges. A second count was made twenty-four hours after the first one. It showed a differential of 78 per cent polymorphonuclears, with a total of 14,500 white cells. The patient feels apparently well, is playful, eats well and sleeps well. She is kept in bed, is given plenty of fluids, and in the beginning of her illness when the urine was markedly acid the alkaline method was used; at the present time she is getting a combination of methenamine and acid sodium phosphate. She was also given the dye treatment. The pus still persists. Is there any special method of treating the pyelitis? Is the autogenous vaccine treatment indicated? What is the maximum limit of liquid consumption in similar cases for a child 6 years old? Is there any special diet to follow? Kindly omit name.

M.D., Connecticut.

ANSWER.—The symptoms enumerated are certainly suggestive of acute appendicitis, and in spite of the pyuria the patient may indeed have had a subacute appendicitis that subsided spontaneously. The fact that she still complains of pain after eating may be significant, more so of a residual appendiceal or other intestinal disturbance than of the urinary tract.

Pyelitis may be present, but the writer does not state the amount of pyuria. The fever may, however, be due to the residual ear infection alone or to a combination of this and the subsiding appendicitis. Infection in two or three areas would suggest the possibility of a low grade septicemia.

Hematuria is occasionally a confusing complication of appendicitis, but it fortunately does not occur frequently. A degree of pyuria may also occasionally be seen with acute appendicitis, and both hematuria and pyuria have been explained on the basis of an extension of the inflammation from a retroplaced appendix to the right ureter. Some years ago, G. L. Hunner called attention to the fact that acute attacks of appendicitis may sometimes be accompanied by pus and blood in the urine when the clinical picture is one of septicemia, and also that acute pyelitis may result from acute appendicitis (acute Pyelitis Due to Acute Appendicitis, *THE JOURNAL*, April 25, 1908, p. 1328).

As long as the ear infection is present, a small amount of pyuria might be expected to persist. If the degree of pyuria is significant (more than 10 to 15 pus cells to a high power microscopic field), further support for the diagnosis of infection of the urinary tract is in order. A catheter specimen of the urine should be examined for red blood cells, albumin and casts, as well as for pus. A urine culture, a blood culture and an estimation of blood urea should be made. A pyelogram and cystoscopic examination may be necessary, perhaps also a roentgenogram of the mastoid area on the affected side.

Bed rest should be continued. Cathartics should be avoided entirely or used with caution. The diet should be confined to liquids and soft foods as long as fever and pain after meals are present. If the diagnosis of pyelitis is confirmed, and if the offending organisms are of the *Escherichia* type, the use of the ketogenic diet may be indicated. (See *Queries and Minor Notes*, *THE JOURNAL*, Oct. 28, 1933, p. 1413, and May 19, 1934, p. 1702.)

LIPOID NEPHROSIS

To the Editor:—Will you kindly inform me of a successful method of treatment for lipid nephrosis that may have recently come to attention. A white boy, aged 5 years, in whom the onset occurred one and one-half years ago, was first hospitalized one year ago. The symptoms occurred at first only during intercurrent infections but became gradually more severe and persistent. He was treated with a high protein diet, urea hydrochloride and thyroid gland; he apparently improved. The edema and ascites disappeared but the urine continued to show large quantities of albumin and occasionally a few red blood cells. At home he did well until an acute infection of the upper respiratory tract brought a return of symptoms, more marked than ever. He has been in the hospital again for the past six months and the edema and ascites seem to resist any diuretic used but subside and increase more or less periodically independent of the medication. He has been relatively free from intercurrent infection during the past six months. The tonsils and infected teeth were removed during his previous stay. The red blood cells are increasing in numbers in the urine, probably indicating a complicating nephritis. Abdominal paracentesis has recently been required to relieve the ascites. The following diuretics were used: urea hydrochloride, ammonium nitrate, theobromine sodium salicylate and salyrgan.

M.D., New York.

ANSWER.—True lipid nephrosis is a relatively rare condition, especially in a child, and such a diagnosis demands certain definite criteria that distinguish lipid from other types of nephrosis. There are three types of nephrosis: 1. Acute nephrosis: This type may arise from chemical poisons (e. g., mercuric chloride), from jaundice, or from certain toxic and infectious processes. It is characterized by oliguria and retention of urea and by little else. Anemia, hypertension, hypercholesterolemia and alterations in serum proteins are absent. Albuminuria may be only slight, and little if any edema and hematuria are noted. 2. Lipoid nephrosis: In lipid nephrosis, hypertension, anemia and hematuria are absent but there is marked albuminuria and edema, a striking decrease in serum proteins and an increase in blood fats, especially in cholesterol, all in conjunction with good renal function. 3. Amyloid nephrosis: In this type of nephrosis, hypertension is also generally absent but there is marked albuminuria and edema, hypercholesterolemia and a decrease in serum proteins. Additional signs of renal insufficiency may be present; for example, a little hematuria, mild or moderate oliguria, and urea retention.

The treatment used so far in this case is quite in accord with the best practice. In addition to removal of foci of infection and to the use of the diet and diuretics mentioned, it is assumed that the patient's salt and water intake has been kept as low as possible, no extra salt being allowed, or the patient restricted to a salt-free diet and to not more than from 600 to 800 cc. of fluid daily. It would be well to have a roentgenogram and a special examination of the sinuses to rule out quiescent sinusitis, an infection sometimes missed in children and considered of more than ordinary importance in nephrotic children. The protein intake can be liberal, if renal function is adequate. As hematuria is present and is increasing, it is likely that the patient is suffering from a nephrotic type of nephritis and not from a true lipid nephrosis; therefore an estimation of the blood urea (or if this is not feasible in a child, of the salivary urea index) would seem advisable before allowing excess protein to be given or before considering the further use of salyrgan, perhaps in combination with other diuretics.

The action of diuretics is characterized at times by variability; a diuretic may fail at one period of nephrosis and succeed at another. If the further use of ammonium nitrate by mouth and salyrgan intravenously in acceptably large doses is unsuccessful, the use of intravenous dextrose (about 100 cc. of a 15 to 20 per cent solution) or repeated small transfusions may be helpful. The purine (xanthine or caffeine) diuretics have apparently been used. Digitalis might be tried if there is any evidence of cardiac insufficiency.

Recently, Hartmann has advocated the use of acacia in cases of lipid nephrosis not responding to other measures.

Diuretics in combinations may succeed, while they may fail when used individually. If considerable ascites is present, the child should not be permitted to lie too flat on the bed. Two or more pillows should be used, as "uremic convulsions," even in the absence of significant azotemia, have been noted in patients with nephrosis and extensive edema who were prone for long periods.

TRYPARSAMIDE AND OPTIC ATROPHY

To the Editor.—A man, aged 66, had a marked arteriosclerosis and a blood pressure of 170 systolic, 100 diastolic. The Kahn test for syphilis was four plus. He had had rather intensive treatment. The drug that he had recently had weekly for a number of weeks was probably tryparsamide. The knee jerks were absent and the Romberg slightly positive; the pupils reacted sluggishly to light. The spinal fluid was normal. The most alarming symptom was that for the past two months the patient's vision had been progressively failing. Ophthalmoscopic examination showed a beginning optic atrophy. Is the tryparsamide responsible for the beginning atrophy in the optic nerve? What is the prognosis in this case? What are the indications for treatment? The man is now being treated merely with bismuth compounds and iodides, as I am afraid to give him either arsphenamine or tryparsamide. Please omit name.

M.D., Illinois.

ANSWER.—L. L. Mayer and R. Dentin Smith are of the opinion that tryparsamide causes no increase in atrophy of the optic disk when syphilis has previously caused changes, that tryparsamide causes no optic atrophy in unaffected disks, and that the drug under careful supervision should have only beneficial effects on the optic nerve. N. K. Lazar (Effect of Tryparsamide on the Eye, *Arch. Ophthalm.* 11:240 [Feb.] 1934) concludes: "The definite loss of vision so soon after injection of tryparsamide leaves no doubt in my mind of a definite toxic effect of the drug in the visual apparatus of certain patients." Emory Hill in the discussion of this paper states there is no serious permanent damage to vision when the drug is stopped as soon as slight damage becomes apparent.

Cases of sudden blindness (twenty-four hours) have occurred following a single injection of a bismuth compound intramuscularly in cases of partial optic atrophy. Many authors have reported ill effects from the use of arsphenamine and neoarsphenamine in cases of partial optic atrophy. The question is unsettled. Satisfactory results have followed the use of the arsenicals unless the patients show decreasing peripheral fields or increasing pallor of the disks. Cases have been checked by the use of these drugs in the stage in which the patients first presented themselves. In cases showing untoward results from tryparsamide it is believed that the changes are due to the syphilis and not to the drug. With a negative serologic examination, most cases remain in the stages in which they are first seen. The indications for treatment are visual disturbances with normal fields, and treatment should be continued if the fields remain unchanged.

TREATMENT OF LATENT SYPHILIS

To the Editor.—The article in *THE JOURNAL*, April 21, page 1267, on the standard treatment procedure in early syphilis, will prove of great value to many physicians. I think that a similar summary of the treatment of late syphilis would be of great help to the general practitioner, who must treat many of these cases if they are to have any treatment. Kindly answer the following for me: Mrs. H., aged 34, came to me, Jan. 3, 1933, with a 4 plus Wassermann reaction. Her only complaint was that the tibial crests were sore and rough. During the first year I gave her twenty-six doses (most of them 0.6 Gm.) of neoarsphenamine, and forty-four 2 grain (0.13 Gm.) doses of bismuth salicylate in oil. At the end of the year the blood Wassermann reaction was 1 plus. Since April 1934 she has had ten doses of the bismuth compound and three doses of (0.45 Gm.) neoarsphenamine. Her veins are difficult to enter with a needle. Is there an efficient method of treatment that does not necessitate the frequent use of intravenous injections or does not use them at all. I would appreciate any suggestions regarding this case.

M.D., Kansas.

ANSWER.—The inquirer will find in at least three textbooks recently published adequate information in regard to the general principles of the treatment of late syphilis. The degree of individualization is such that it is difficult to summarize without excessive detail. The Cooperative Clinical Group has, however, published accounts of the treatment of latent syphilis, which are available through the United States Public Health Service, Bureau of Venereal Diseases.

The patient described stands at the moment more in need of adequate examination than in need of further treatment. It

is essential to determine the status of the nervous system by a complete spinal fluid examination, and of the cardiovascular mechanism by a careful physical examination, a teleroentgenogram, fluoroscopic visualization of the aorta and an electrocardiographic examination. The blood Wassermann reaction is, in some respects, the least important item in the case. The patient has received at least the average amount of treatment appropriate to a latent infection. If the soreness of the tibial crests was due to a periosteal or osteoperiosteal lesion, she must be regarded as having late bone syphilis and the heavy metal therapy should be continued for approximately another year. If her treatment is to be confined to intramuscular procedures, bismuth arsphenamine sulphionate once a week for forty injections, or a continuance of bismuth salicylate in courses of ten injections separated by intervals of from eight to twelve weeks during which the patient receives potassium iodide would be an average appropriate procedure in the absence of contraindications or evidence of more serious forms of involvement.

The fact that the patient is a woman must be kept in mind with particular reference to pregnancy, and if she becomes pregnant treatment with neoarsphenamine and a bismuth compound should be resumed for the protection of the child, in accordance with the principles applicable to this aspect of syphilis.

INTERMENSTRUAL PAIN AND OVULATION

To the Editor.—A woman, aged 25, married, never pregnant, complains of acute pain, which has recurred regularly every month, midway between her menses, for the four years of her married life. It is localized in the lower right abdominal quadrant. It is sudden in onset, endures for two or three hours and ceases as suddenly as it begins. A soreness remains at the site for two days. For two days preceding and following the pain she regularly notes an opaque leukorrhea, which occasionally shows flecks of blood. It is never present at other times. The patient has never been seriously ill; no history of pelvic inflammatory disease was obtained. Her menses began at 15 and were rather profuse, recurring at slightly irregular intervals, associated with cramps and occasional vomiting. The intermenstrual pain is not associated with vomiting. Examination of the external genitalia is negative. The uterus is of normal size, anteflexed and moderately retroverted, and is not fixed. There are no palpable masses or palpable abnormalities of the tubes or ovaries. The examination is attended by considerable tenderness on the right side of the pelvis. The patient is apprehensive of the pain and states that she would be perfectly well were it not for that. She is completely disabled at the time. No abnormalities have been found in the urine or blood. There is no fever. Will you kindly suggest the probable diagnosis and treatment in this case? Please omit name and address.

M.D., Iowa.

ANSWER.—The pain described is that which is termed "mittelschmerz" by the Germans and was called intermenstrual pain by Priestley. It recurs regularly at the same time in the intermenstrual cycle, but usually about midway between each two menstrual periods. The condition is not common and a diagnosis of intermenstrual pain should not be made unless the pain recurs at about the same time for at least a number of months. During periods of amenorrhea such as pregnancy and lactation, the attacks of pain are absent. The pain, which is not characteristic, is usually confined to one iliac fossa but sometimes to both. It usually lasts a few hours but may endure for days, although in the latter cases it is not steady. In about 50 per cent of the cases of intermenstrual pain there is a vaginal discharge present during the attacks of pain. The discharge may be watery, mucous, yellowish and occasionally bloody. In some cases in which the discharge is bloody or blood stained there is a local cause for the bleeding, such as a polyp or submucous fibroid. However, as C. G. Hartman (*Am. J. Obst. & Gynec.* 19:511 (April) 1930) points out, the bleeding associated with intermenstrual pain may be a pathologically accentuated expression of a phenomenon that occurs in some animals. Many individuals regard as menstruation the visible periodic bleeding of bitches. This designation is wrong, as evidenced by its time relation to ovulation. The bleeding precedes and accompanies ovulation and hence should be called "proestrous bleeding." A similar and homologous bleeding occurs at the cotyledons of the cow. The final proof of the homology is Hartman's discovery of the intermenstrual bleeding in the monkey, which frequently occurs in the middle of the menstrual cycle. It is usually microscopic, is always less than in the dog, and is in both species a concomitant of the congestion that accompanies the presence of a maturing follicle. Hartman wonders whether future study will not show that intermenstrual bleeding in the human female is physiologic and normal rather than abnormal.

Most of the women afflicted with intermenstrual pain are young, but the attacks of pain rarely make their appearance with the onset of puberty. The attacks may recur for many

years, even lasting throughout the entire reproductive period. A large proportion of these women are sterile. The menstrual periods are usually normal and, if dysmenorrhea is present, it is usually much less severe than the intermenstrual pain. Many, but by no means all of the women who suffer intermenstrual pain have pelvic disease.

The cause of the pain is undoubtedly the process of ovulation, which occurs at about the middle of the intermenstrual interval. Hence the pain is associated with the menstrual period that follows the pain and not the one which precedes it. It is difficult to say what factors are involved in the mechanism of production of the pain. Normal ovulation is not associated with pain.

The treatment of intermenstrual pain is unsatisfactory. In not one of the sixty-four instances collected from the literature by Kelly was the pain self limited (Kelly H. F.: *Medical Gynecology*, New York, D. Appleton & Co., 1908). Of course, if any abnormality in the pelvis is present, it should be corrected by medical, physical or surgical means. The pain itself must be treated empirically by means of rest in bed, local heat and mild analgesic drugs. In many instances, narcotics such as codeine and morphine must be given; but they must be used with great caution. Kelly states that removal of the ovary on the side where the attacks of pain always occurred brought about relief in only two out of four cases. Whether any of the new hormone preparations will bring about a cure is highly conjectural.

PROGRESSIVE FATIGUE AND HYPERTENSION

To the Editor:—A white man, aged 45, states that for three years he has been becoming more and more constantly tired. Aside from this his history is negative. Physical examination is negative except for a slight hyperactivity of the knee jerks and a blood pressure of 148 systolic, 110 diastolic. Urinalysis is negative except for a few epithelial cells and a few white cells. Hemoglobin is 85; the red cells number 4,800,000 and the white cells 7,800. The basal metabolic rate was -4 and -2.5 on two tests. The Wassermann reaction is negative. A trial of thyroid therapy gave no results. Please omit name. M.D., Illinois.

ANSWER.—The two positive observations in this case are progressive fatigue and early essential hypertension. As a rule, subjects in the early stage of essential hypertension do not become fatigued easily. Many are extremely resistant to abnormal degrees of mental and physical fatigue. States of exhaustion are more prone to occur among patients who have low blood pressure. It is likely that there is no endogenous element underlying the patient's complaint. It is more probable that exogenous factors, such as work, worry and mental stress and some constitutional inadequacy rather than any derangement in the body, are causing the state of fatigue. If low metabolic rates or advanced grades of focal infection are absent, and if organic disease is eliminated, the condition of patients may improve when assured that their physical functions and organs are not diseased, as this removes a factor of anxiety which accentuates fatigue. Adequate vacations, with changes in environment, more sleep, midday rest and week end periods of relaxation, combined with mild forms of physical exercise, bring about a feeling of well being. If this treatment does not prove efficacious, glycine might be given a trial for a period of two or three months. Reduction in the amount of tobacco used or elimination of other deleterious habits may be advised, although too drastic changes in habits should not be urged.

CALCIUM DEPOSITS IN BRONCHIAL TUBES

To the Editor:—I have a patient who has calcium formations in the bronchial tubes. For fifteen years she has coughed up calcium stones at intervals. The condition has been diagnosed as broncholithiasis. The suggested treatment was rest, tonics and codeine for the cough. The patient does not improve with this treatment and I am asking you for further information on the care and treatment of the disease. The climate here is damp and cold. Would a dry warm climate be beneficial to the patient? Please omit name and town. M.D., Missouri.

ANSWER.—Abnormal deposits of calcium occur in the tissues of the chest under much the same conditions as in other portions of the body. Abnormal calcification occurs at the site of hyalinized tissue in regions of old suppuration or hemorrhage and also in cases in which there is excessive mobilization of calcium in diseases of the bones. Metastases in malignant disease may become calcified. In the chest, extensive calcification of the pleura has followed empyema. A frequent site of localized calcification and perhaps that most frequently associated with expectoration of calculi is the glands at the hili of the lungs. Smaller calcified nodules are commonly seen in roentgenograms of the lung fields. Many of the lesions are associated with tuberculosis, but in a considerable number of the cases cited in the literature no tuberculosis was demon-

strable and after expectoration of calcareous masses the patients recovered and remained clinically well for years. In other instances a period of good health was followed by recurrence of the expectoration of calculi.

A calcareous mass may cause erosion of an adjacent bronchus, with subsequent expectoration of calcified fragments. These fragments may vary in diameter from 1 mm. to 1 cm. and are sometimes larger. Their composition is usually that found in calcium deposits elsewhere, approximately 85 per cent calcium phosphate and 15 per cent calcium carbonate. The expectorated masses have been called broncholiths, bronchial calculi and lung stones. In some instances a calculus becomes fixed in a bronchus, causing retention of secretions, formation of an abscess or local pulmonary inflammation.

In the case cited, some information as to the possible nature of the underlying process should be supplied by roentgenograms of the chest, which would perhaps reveal evidence of an old calcified pleura or of lesions at the hilus. Four cases have been reported by J. J. Lloyd (Broncholiths, *Am. J. M. Sc.* 179:694 [May] 1930), in one of which a calcified mass at the right hilus, demonstrated by a roentgenogram, was shown to have disappeared in later films taken after the expectoration of broncholiths.

The further course of the condition described in the query will depend to a considerable extent on the presence or absence of active clinical tuberculosis. The bronchoscope might be of value in diagnosis and possibly, as suggested by Chevalier Jackson, in treatment. A warm dry climate would be likely to favor recovery in the presence of an associated tuberculosis or in nontuberculous chronic bronchitis.

Among other references the following two articles may be consulted:

Pritchard, J. S.: Calcareous Degeneration Found in the Thorax, *Arch. Int. Med.* 32:259 (Aug.) 1923.

TREATMENT OF STERILITY

To the Editor:—Can you give me suggestions regarding a case of sterility? A man, aged 24, has been married four years. As a boy, he had mumps with orchitis; there is no history of venereal infection. Condom specimens of semen show many inactive spermatozoa. The prolonged administration of emplants of orchic substance (Parke, Davis & Co.) produces improvement, but this is not maintained. The wife, aged 23, has fairly regular but scanty menstrual periods. The uterus is rather of the infantile type. There is no erosion of the cervix and no definite cervicitis. Postcoital semen removed from cervix shows a hostile reaction of the cervical secretions to the spermatozoa, no active spermatozoa being found. The cervix has been dilated. Small doses (0.1 cc.) of anterior pituitary-like principle from pregnancy urine have been given three times a week for two weeks during each intermenstrual period. Semen has been introduced into the uterine cavity through a cannula without results. I should appreciate any help you can give me. Kindly omit name. M.D., Georgia.

ANSWER.—Condom specimens are generally unsatisfactory. It is far better to have the husband ejaculate the semen into a small, clean, wide-mouthed jar or bottle at the time of the orgasm. A friction specimen is more satisfactory than a condom specimen. If no motile spermatozoa are seen after repeated examinations of specimens in containers and the semen obtained from the vagina and cervix after coitus, the husband should be investigated by a urologist to see whether the condition can be rectified. Underdevelopment of the uterus is frequently a cause of sterility.

In spite of the excellent results observed in animal experiments with the use of injections and implantations of pituitary substances, the results in human beings have not been highly satisfactory. However, the outlook for this type of therapy is encouraging.

No mention is made of a tubal patency test. This test should be performed before semen is injected into the uterine cavity because, if the uterine tubes are not permeable, not only will pregnancy fail to take place but infection may result. The tubal patency test should not be done unless it is demonstrated that the spermatozoa in the husband's semen are satisfactory.

If the spermatozoa are satisfactory and the tubes are patent, it may be advisable to perform a dilation and curettement on empirical grounds. Not infrequently, pregnancy follows this operation.

Semen should not be injected into the uterine cavity unless a large proportion of the spermatozoa are actively motile. Furthermore, in most instances the semen must be injected many times before fertilization takes place. The most favorable time for uterine insemination is during the middle ten days between menstrual periods, because ovulation occurs during these ten days in the vast majority of women.

EDEMA OF ANKLE DURING MENSTRUATION

To the Editor.—A woman, aged 28, had a miscarriage, Sept. 1, 1933. Since that time she has had severe pain in the right ankle. The pain starts one day before the menstrual period and lasts for about six days. The pain is severe enough to cause the patient to limp and is continuous, whether she is on her feet or resting. There is also swelling between the achilles tendon and the external and internal malleolus. There are no varicose veins present and the leg is apparently normal, the only swelling being between the achilles tendon and the malleolus. Between periods she has occasional twitching in this region. The pain and swelling have continued with each menstrual period since the miscarriage. The swelling is not of the edematous type. I have treated her for some time but have not been able to obtain any results. Will you kindly tell me the cause of this condition, and also the proper treatment? Please do not mention my name.

M D, Michigan

ANSWER.—Assuming that the patient had an uneventful recovery from her miscarriage, it is difficult to see any connection between the miscarriage and the present complaint. Likewise there is no apparent direct relationship between the menstrual periods and the pain and edema in the ankle. As is well known, menstruation does not simply consist of uterine bleeding but affects all parts of the body. This results in a number of other signs and symptoms, many of which are disagreeable and troublesome. Among them are pains in the pelvis, pain in the breasts, headaches, circulatory disturbances, lassitude, nervousness, bladder irritability, interference with the regularity of the bowel movements, overactivity of the skin, and skin eruptions. In other words, the process of menstruation involves the entire body and if for some reason the right ankle is a locus minoris resistentiae, it may present the features this patient experiences when a change takes place in the body each month. The edema and the pain are most likely of circulatory origin. Since the exact cause of the pain is unknown, no specific therapy can be recommended. The patient should be made as comfortable as possible by physical measures and mild analgesic drugs. Even though there is an association with the menses, the use of hormone preparations would be highly speculative. Most likely the symptoms will disappear spontaneously just as usually happens when similar disturbances arise in connection with the menstrual periods.

IDENTIFICATION OF SEMINAL STAINS

To the Editor.—A man was found unconscious with bullet wounds in the upper right part of the chest, the upper right part of the abdomen (the bullet coursing backward and downward toward the sacral region), and another through the scrotum. The undertaker, on examining the victim's clothes found, as he thought, stains due to a seminal discharge. The prosecuting attorney contends that this emission was due to the bullet wounds, in contradiction to testimony for the defense that the victim was having illicit relations with the murderer's wife just prior to the shooting, in spite of the fact that the victim's clothes were all buttoned up and evidence points toward his becoming unconscious immediately on being shot. The question is, Is it possible to be shot in the region of the pelvis or scrotum with resulting seminal discharge? Kindly omit name.

M D, Kentucky.

ANSWER.—That emission of semen by ejaculation can follow a gunshot wound of the pelvis seems unlikely. On the other hand, semen might run out through a bullet wound involving the seminal vesicles. Let it be noted that the seminal nature of a stain cannot be determined by inspection only—spermatozoa must be demonstrated microscopically and/or seminal protein demonstrated by a specific precipitin test before one can say that a given stain is due to semen. Finally, in the case in question, assuming that the stains are seminal, why might they not have been deposited some time before the episode that led to the fatal shooting?

MERCURY POISONING HAZARD

To the Editor.—Will you please give me your opinion as to whether a laboratory worker who is handling mercury continuously, about six hours a day, five days a week, would be subject to mercurial poisoning? The mercury is used in liquid form from a buret in testing the tensile strength of paper. The room is well ventilated and he does not touch much of the mercury with his hands. Kindly omit name if this appears in THE JOURNAL.

M D, Wisconsin.

ANSWER.—Mercury poisoning from the exposure described is possible. Traces of mercury vapors continually arise from the surface of the metallic mercury. Novy, years ago, established the fact that the mercury in manometers used in connection with the culturing of various organisms gave off sufficient vapors to alter or inhibit the growth of these fungi or bacteria. The presence of mercury poisoning in this paper tester would be favored by the presence of one or more of the following cardinal manifestations: salivation, gingivitis, dryness of the throat, blue discoloration of the gums, muscular tremors and erethismus. Mercury in the atmosphere may be demonstrated through the use of mercury test papers, which

may be applied in a manner as simple as that in which litmus paper is used for the determination of acids and alkalis. A good description of mercury poisoning may be found in a publication by Wade Wright (*J. Indust. Hyg.* 4:296 [Nov.] 1922).

PELVIC MEASUREMENTS

To the Editor.—Please give me the average or normal pelvic measurements, especially the intercristal, interspinous, intertrochanteric, and external and internal conjugate. With what measurements do you consider cesarean section advisable? Please omit name and address.

M.D., California.

ANSWER.—The average external pelvic measurements are: interspinous, 26 cm.; intercristal, 29 cm.; intertrochanteric, 31 cm.; external conjugate, 20.5 cm.; internal conjugate, 11 cm.; diagonal conjugate, from 12.5 to 13 cm.

Of these measurements the internal conjugate and diagonal conjugate are the only ones of real value, but even they may not be used alone in deciding the necessity for cesarean section. The internal examination and the roentgenographic evidence are necessary in making up one's mind to perform such an important operation.

Repeated emphasis must be put on the fallacy of the external pelvic measurements.

The size of the baby must also be considered and finally, except in extreme contraction, a sufficient test of labor should be given.

DIGESTION OF MEAT

To the Editor.—Kindly inform me through THE JOURNAL about the duration of digestion of meat, such as steak, in the stomach and in the small intestine, and the total time interval between ingestion and absorption. Please omit name.

M D, Chicago

ANSWER.—Observations on these phenomena are so fragmentary as to the materials ingested, the species of animal used and the methods of observation as to render it almost impossible to give a forthright answer to these questions. Several authorities have been consulted, both personally and through their writings, with the following results, which must be evaluated in the light of the foregoing.

Meat leaves the stomach in from one to two and one-half hours. It continues to undergo digestion in the small intestine for about three hours, depending on the amount ingested. By the end of this time it is leaving the ileum, beyond which little absorption occurs. The total time between ingestion and the absorption of meat therefore ranges from four to six hours.

BRUISES OF SHIN

To the Editor.—I have a patient who bruised her shin fourteen years ago. At times an ulcer forms over the tibia at the site of the injury. This is extremely painful. Hot, wet dressings and staying off the feet will allow it to heal. Is there anything that can be used on it? What is the best treatment for these bruises over the shin bone when they occur?

DeVERE RITCHIE, M.D., Harrisburg, Pa.

ANSWER.—The circulation of the skin of the lower half of the leg over the tibia is poor, and following any injury slow healing often results.

Avoidance of infection and phlebitis favors early healing. Varicose veins increase the tendency to ulceration.

With any wound or ulcer of the leg, supporting bandages and keeping off the feet for a few days are of great help in healing.

Narrow strips of adhesive plaster applied across the chronic ulcer promote epithelization underneath. They are changed about twice a week and covered with a little gauze to absorb any secretion.

If varicose veins are present, they may be treated by injection or excision if necessary.

Skin grafts after excision of the ulcer and the fibrous tissue are indicated when other measures fail. A Wassermann test should always be done.

APHTHAE RESISTENTIA

To the Editor.—Could you advise me of some new methods to try in treating a case of chronic aphthae, or periadenitis mucosa necrotica recurrens? The case I am treating is that of a woman about 25 years old. She has had the condition off and on for about fifteen years. At times the lesions are numerous and severe and occasionally involve the vagina. She states that one of her children, a brother, her father and a grandmother are all afflicted with this disease. She gives a definite history of rheumatic fever and St. Vitus dance. Please omit name and address.

M D., New York.

ANSWER.—As implied in the names, periadenitis mucosa necrotica recurrens, or aphthae resistentia, is a difficult disease to treat, clearing at times with or without treatment but nearly

always recurring. All authorities agree that it yields to arsenic more regularly than to any other drug. Ormsby has reported cases that cleared up with treatment with arsenphenamine, but this drug failed in other cases. Howard Fox mentioned prompt improvement with roentgen therapy. Sutton, who originally described the disease in this country, used hygienic measures, outdoor sleeping, light exercise, easily digested, nourishing food in plenty, cod liver oil, iron and arsenic with good effect; the latter drug is possibly responsible for most of the benefit. The disease is familial, as in the case under discussion, seems to have a nervous element in it, and the mild lesions resemble ordinary canker sores. Whether it has any relation to the latter disease, or whether the resemblance to tuberculids mentioned by Fordyce in his discussion of Howard Fox's case means anything, has not been determined.

TUMOR OF THE KNEE JOINT

To the Editor:—A boy, aged 5 years, was brought to me because of a fluctuating tumor, about the size of a small hen's egg, in the left popliteal space. Aspiration showed a clear, viscid fluid. It was treated by incision and drainage and swabbing out of the cavity with a strong tincture of iodine, and drainage. The wound closed without infection in about ten days and the cavity seemed to have been obliterated. Now after a period of three months the tumor has reappeared and is gradually increasing in size. Advice is requested as to the probable nature of the tumor and whether excision is indicated. Please omit name and address.

M.D., California.

ANSWER.—It may concern an outpouching or hernia of the knee joint itself or an inflammation in some bursa in this region. After puncture, rest and fixation may result in cure. It must be borne in mind that a cyst in the popliteal region often opens into the knee joint. In some of the cases, tuberculosis is at the bottom.

THYMIC DEATH

To the Editor:—Concerning the query on "Thymic Death" in *THE JOURNAL*, September 15, page 856, much confusion on this subject has arisen because of classifying any unexplained death in children as "thymic." Thus, if the "lungs were completely atelectatic," the diagnosis in the case in question is suggestive of massive atelectasis due to aspirated mucus rather than of "thymic death."

In consideration of the causes of "thymic death," such theories as death due to mechanical pressure on the trachea and blood vessels, hemorrhages into the pons and asphyxiation due to contracting uterine walls should be mentioned only from a historical point of view, as they are no longer accepted.

There is increasing evidence that the enlarged thymus, like all lymphoid tissues, is a part of the allergic constitution and that sudden death is due to allergic shock (Waldbott, G. L.: So-Called Thymic Death, *Am. J. Dis. Child.* 47: 41 [Jan.] 1934). This theory also conforms well with the familial occurrence of "thymic death." I have the records of four families in which "thymic death" occurred in more than one child.

Concerning roentgen treatment of the thymus, it is well to remember that death may occur in thoroughly irradiated babies, as my records show. This, however, does not speak against the fact that roentgen therapy of the gland is still the best method available.

GEORGE L. WALDBOTT, M.D., Detroit.

DEFORMITY OF RECTUM WITH PAIN AFTER REPEATED INFECTION

To the Editor:—I was much interested in your answer to M.D., Texas, in *Queries and Minor Notes* (*THE JOURNAL*, September 1, p. 699) concerning inflammation of the anal canal. Although I agree that the disease in question can hardly be called a neuralgia, I do not believe that the trouble is due to a deformity of the rectum. The history, symptoms and proctoscopic observations in this case are, in my opinion, very suggestive of gonococcal infection of the anal ducts. The latter are preformed structures of varying length which extend from the crypts of Morgagni into the wall of the anal canal. Their microscopic changes and clinical significance were described by Tucker and Hellwig in *Surgery, Gynecology and Obstetrics* (58:145 [Feb.] 1934). I agree with you that the condition will not be cured by conservative treatment. In my cases of chronic gonococcal infection of the anal ducts I have obtained lasting cures only after complete excision of the infected ducts.

CLAUDE C. TUCKER, M.D., Wichita, Kan.

IMMUNITY IN TULAREMIA AND UNDULANT FEVER

To the Editor:—In answer to the query by Stanley M. Gates (*THE JOURNAL*, September 15, p. 861) you stated that tularemia and undulant fever appear to be good examples of diseases that develop final immunity with each succeeding exacerbation. In reference to tularemia, there are no authenticated reported cases of reinfection. Occasionally an individual who has had the disease may again manifest some of the lesser phases of the infection, which may be regarded as reinfection, recurrence or second attack. These manifestations of tularemia are rare. Francis makes the statement that he has not heard of a frank out-and-out second attack of tularemia. The immunity in tularemia is regarded to be the most complete of any of the infectious diseases.

HARRY L. BAER, M.D., Pittsburgh.

Maryland June Examination

Dr. Henry M. Fitzhugh, secretary, Board of Medical Examiners, reports the written examination held in Baltimore, June 19-22, 1934. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and sixty-three candidates were examined, 154 of whom passed and 9 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1933) 82.1,	(1934)	87.5
George Washington University School of Medicine....	(1933) 86.7, 87.4, (1934) 81.1		86.4
Georgetown University School of Medicine.....	(1932) 83.3, (1933) 77.1, 78, 81.7, 83.5, 84.3, 85.7, (1934) 78.2, 79.1, 79.2, 79.4, 80.4, 80.4, 81.3, 82, 82.2, 83, 83.3, 83.5, 83.6, 85, 85.7, 85.8, 86.2, 88.2, 90.3, 90.4		81.1
Howard University College of Medicine.....	(1933) 77, 80.2, 81.5, 83.5,		83.8
Tulane University of Louisiana School of Medicine....	(1933)		81.5
Johns Hopkins University School of Medicine.....	(1931) 81.2, (1932) 86.4, 88.5, (1934) 76.7, 78.3, 79.4, 79.7, 79.7, 80.3, 81.3, 82.1, 82.2, 82.6, 84.1, 84.3, 85.2, 85.6, 86, 86.2, 86.2, 86.7, 86.8, 86.8, 87.5, 87.5, 87.6, 88.2, 88.3, 88.3, 89, 89.4, 89.7, 89.8, 89.8, 90.1, 91.6, 92.5		80.4
Univ. of Md. School of Med. and College of P. and S. (1932)	(1933) 87.5, (1934) 80, 80, 81, 81.5, 81.6, 81.6, 82.1, 82.3, 82.7, 82.8, 83.3, 83.6, 84, 84.3, 84.5, 84.6, 84.8, 84.8, 84.8, 85.1, 85.2, 85.4, 85.4, 85.4, 86, 86.3, 86.3, 86.4, 87, 87.3, 87.4, 87.4, 87.5, 87.6, 87.6, 87.7, 87.8, 88.2, 88.3, 88.4, 88.5, 88.7, 89, 89.3, 89.3, 89.3, 89.4, 89.4, 89.7, 89.8, 90.2, 90.4, 90.5, 90.5, 91, 91, 91.1, 91.6, 92.4, 93		88.1

† Permitted to come before the board for examination by special act of legislature.

Book Notices

Parasitism and Disease By Theobald Smith Published on the Louis Clark Vanuxem Foundation Cloth Price, \$2 Pp 196 Princeton, Princeton University Press, 1934

The director emeritus of the department of animal pathology of the Rockefeller Institute of Medical Research is abundantly qualified by long contact with research on parasitism and disease to make a critical presentation of this subject in the light of his long and varied experiences with the experimental analysis of the factors in disease and its prevention and control His discovery of the relation of the cattle tick to the Texas fever of cattle opened the relation of insect vectors to the transmission of disease of parasitic origin, a relation that was basic to the later analysis and solution of the causes of malaria, trypanosomiasis, leishmaniasis, typhus fever and other insect-borne afflictions of man and the domestic animals.

The lectures here expanded and modified in book form were delivered on the Louis Clark Vanuxem Foundation. The book lacks the illustrations that accompanied the lectures but retains the freedom from citation of authorities and documentation of sources which the platform demands Both of these features tend to disappoint the technical reader, though this is in part assuaged by the greater simplicity of presentation and a certain directness in criticisms and the statement of conclusions

The author's recognition that animal and human parasitic afflictions present a common series of problems for analysis requiring similar, if not identical, methods of attack, with solutions equally applicable in therapy, prevention and control alike in veterinary and human medicine, presents a point of view much needed in these days of subsidized organizations of antivivisectionists. A continuous campaign of education of the public by the medical profession and the nonprofessional press is much needed. Dr. Smith also makes no distinction between animal parasitology and bacteriology in his arrangement of subject matter and his topical discussions The neglect of parasitology in premedical and clinical medical instruction has given a bacteriologic slant to the practice of medicine which all too often limits diagnosis and therapy.

The book opens with a chapter on the derivation of the parasitic mode of life from the predatory one. This is followed by a discussion of the various patterns of life cycle, all of which involve four important stages; namely, adjustment and adaptation to invasion, to multiplication, to emigration or passive discharge, and to transfer to fresh hosts These four demands are met in various ways, each matched against the resisting powers of the host.

The second chapter deals with aberrant parasitisms, which are not regarded as insignificant accidents but rather as the most important factors in the evolution of both parasitism and disease. Aberrance is the adventurous element in the life of the parasite, which leads either to death or to new conquests. Establishment in new hosts paves the way for the formation of new races and varieties, for the new host modifies and molds the invader until a new equilibrium has been established. Aberrance of parasites is furthermore responsible for the

development of disease whenever they reach a more yielding host. Most epidemics or pandemics are probably due to strayed parasites. A study of epizootics among small experimental animals kept together in large numbers tends to show that such diseases are most virulent at the start and gradually change their characters, becoming less infectious, more chronic, non-fatal, and topographically altered as regards the incidence of lesions. The epidemic is probably the first sign of a straying of parasites from either near or more distantly related hosts to new hosts not previously infected, or from an immune group to a susceptible group of the same species or race.

The chapter on the host-parasite conflict analyzes the factors in the battle that ensues when the parasite grows or multiplies within the host. "This is the stage to which medical science has given most attention, and it is the one in which disease as well as cure from disease is generated." Here is found a discussion of racial susceptibility, endemicity, infantile susceptibility, bactericidal ferments and their sources, alexin and opsonin, and other antialien activities of the host and, on the other hand, of the toxins, aggressins, capsules and other envelopes of bacteria and of the cuticula of worms and the envelopes of their ova. The cuticula is nondigestible. The living cells of the parasite are protected from the digestive ferments of the host by an intracellular antidigestive mechanism, which death of the parasite disrupts. The patterns of host-parasite relations are modified by differences in host species, races and individuals, and by their environment, by variations in parasites induced by the environment of artificial cultures, by differences due to stages of adaptation in the evolution of the parasitic mode of life, and by differences due to naturally occurring or artificially induced aberrant parasitism. Moreover, there is no generally uniform order in which the various antialien activities are brought out by the reciprocal stimulation of host and parasite. All one can do is to catalogue these activities in the individual and utilize them in the comparative study of types of parasitism. The forces of the host tend in one direction, destroying or rendering harmless the parasite. The parasite has its mechanism set for multiplication or increase in size. Both involve processes of digestion and assimilation. The host, however, is not dependent on the products of such digestion, whereas the parasite is completely dependent. The host by simply checking the parasite's growth activities has protected itself sufficiently. The parasite, on the other hand, must be able to overcome the antialien forces of the host, in at least a circumscribed territory, by destructive or neutralizing processes while it increases in numbers or develops to maturity. The parasite's ammunition consists of a variable number of factors, such as metabolic products or toxins and such as are released by disintegration of some of the parasites, also special metabolic products of the host species which may be favorable to the multiplication and growth of parasites, enveloping protective substances, capsules of varying degrees of consistency and reproductive activities, and finally ectoplasms or limiting membranes of specific permeability or resistance to digestion. The host, on the other hand, has certain general lytic or digestive powers and the capacity to develop at varying rates antibodies that neutralize toxins and such as paralyze the growth activities of the parasite and envelop and immerse it.

Phagocytosis has played a part in the evolution of parasitism, because there has been interposed between the general antialien activities of the host and the vulnerable evolving parasite a new substance in the form of a protecting capsule or of a new state of the surface of the parasite. This demanded the formation of specific antibodies by the host and also the adaptation of certain normally phagocytic cell groups or the interment and gradual destruction of the parasite.

In the chapter on variation and mutation in parasitic organisms, the author states that the "work of the past generation has revealed a fundamental stability of the characters of micro-organisms with restricted variability" and is somewhat non-committal on the validity of the ultraviolet forms of the bacteria.

In his theoretical discussions he accepts natural selection, but throughout the book he is a thoroughgoing Lamarckian with regard to potency of environmental factors in the evolution of parasitism and host-parasite relations.

In the chapter on survival and host-to-host movement one finds a survey of this interesting aspect of parasitism, with a discussion of antepartum and postpartum transfer through the placenta and milk respectively; of the transfer of antibodies in the early colostrum of the cow in the first two days and the persistence of the protection for only several months; of the inheritance of parasites in insects by way of the ovum; of infection by droplet from the respiratory tract, by insect vectors, and by contamination; of the function of the carrier in the spread and maintenance of communicable diseases; and of the relation to human diseases of domesticated animals and others, such as rats and other rodents associated with man.

The chapters on epidemiology and on the utilization of discoveries contain a review of the relations of epidemics to civilization and an assessment of values of the achievements to date both for public health and sanitation and for personal hygiene.

This book should be read and digested not only by every public health administrator, physician and nurse but also by the medical practitioner. The layman seeking a general picture of the relation of communicable diseases to society will find the book readable and informing. The biologist will appreciate the comprehensive picture which it presents of disease in its relation to the organism and to the evolutionary process.

How to Use a Medical Library: A Guide to Research for Practitioners, Research Workers and Students. By Leslie T. Morton, Associate of the Library Association. Boards. Price, 2s. 6d. Pp. 70. London: John Bale, Sons & Danielsson, Ltd., 1934.

The author of this volume is assistant in the Library of the Royal College of Medicine. He is a firm believer in the idea that those who use libraries should prepare their own bibliographies. The author describes the development of various medical indexes and discusses uses of these indexes and the location of periodical literature, and then the compilation of medical bibliographies. He also describes the methods of using card catalogues in medical libraries. Two appendixes list the available indexes and abstracting journals and the medical libraries of Great Britain. There is also a bibliography of works on the consultation of medical literature.

Death Rates by Occupation Based on Data of the U. S. Census Bureau, 1930. Edited by Jessamine S. Whitney, Statistician, National Tuberculosis Association. Boards. Price, \$1. Pp. 32. New York: National Tuberculosis Association, 1934.

All who are interested in the trend of death rates by occupation or who have use for comparative data pertaining to the relative importance of certain specified causes of death in selected occupations will welcome these compilations. Although the tables do not contain data covering the entire United States, accurate figures are presented for a limited area. This volume may well serve as an introduction to a complete tabulation of census figures on a subject that is vital in any study of industrial hygiene and workmen's compensation. If death rates according to occupation can be used to some degree to indicate the relative risk in various industries and serve to stimulate more scientific and concerted efforts to reduce these hazards, the preparation of these data will have served a definite purpose in individual and community welfare.

Lumbalanästhesie in der Geburtshilfe und Gynäkologie mit besonderer Berücksichtigung der Biochemie des Liquors und der Blutliquorschanke. Von Dr. Ernst Preiszecker, Assistent der II. Univ.-Frauenklinik Wien (Prof. W. Welbel). Mit einem Vorwort von Prof. Dr. W. Welbel. Cloth. Price, 7.50 marks. Pp. 76, with 5 illustrations. Vienna: Wilhelm Mau-drich, 1934.

In this book the author reviews the history of spinal anesthesia, the biochemistry of the cerebrospinal fluid, the pharmacology of the drugs used for spinal anesthesia, the technic of lumbar puncture and spinal anesthesia, the use of this form of anesthesia in obstetrics and in gynecology, and the effect of spinal anesthesia on the intermediary metabolism. He advises against the use of morphine and other alkaloids preliminary to the use of spinal anesthesia because all alkaloids depress the respiratory center. He employed nupercaine in 1,200 cases and prefers the sitting posture for the insertion of the anesthetic. However, in pregnant women near or at term, the lateral position must be employed. The sensitiveness of gravid women to spinal anesthetics is definitely increased, because during gestation there is a greater tendency toward bleeding, an

increased permeability of the blood vessels, a more ready transfer of material from the cerebrospinal fluid into the general circulation, a diminished pulmonary capacity, and a sudden filling of the splanchnic vessels after extraction of the child. In spite of this the author believes that spinal anesthesia is highly suitable for obstetric operations, especially cesarean sections. However, pregnant women who have cardiac disease should never be given spinal anesthesia. The author maintains that spinal anesthesia cannot supplant twilight sleep because it is too risky. In the series of gynecologic cases reported, satisfactory anesthesia was induced in 91.8 per cent. To the rest, ether had to be given. This book should prove valuable to all who are interested in spinal anesthesia.

A Doctor Studies Crime. By Perry M. Lichtenstein, M.D., LL.B., Medical Assistant, District Attorney, County of New York. Cloth. Price, \$3. Pp. 263. New York: D. Van Nostrand Company, Inc., 1934.

The author of this volume was for over eighteen years resident physician of the Tombs in New York and for nearly three years medical assistant of the district attorney. His discussion of crime is therefore based on study of several hundred thousand people accused of criminal acts. His book is enlivened by many anecdotes of the great and near great criminals with whom he has had contact. The chapters of the book discuss the prison physician, narcotic addiction, the relationship of mental and moral defects and of insanity to crime, the uses of probation, the detention prison, court procedure and the penal institution. This is a first hand account of the work of the prison physician, which may be read with interest by every one interested in crime and its detection and also by those interested in prison reform.

Common Skin Diseases. By A. C. Roxburgh, M.A., M.D., B.Ch., Physician in Charge of the Skin Department and Lecturer on Diseases of the Skin, St. Bartholomew's Hospital. Second edition. Cloth. Price, 16s. Pp. 369, with 136 illustrations. London: H. K. Lewis & Company, Ltd., 1934.

This edition has been enlarged by the inclusion of chapters on congenital disorders of the skin, atrophies and scleroses, vesicular and bullous eruptions and erythrodermias. The addition of a goodly number of reproductions of clinical photographs and photomicrographs has enhanced the attractiveness of the book. The point of view of the general practitioner has been preserved by emphasis on differential diagnosis and by omission of those methods of treatment that ordinarily are to be had only in specialists' offices. It is unfortunate that the formulas are not given in the metric system as well as in the older one. Taken as a whole one must give praise to the printers for the excellence of the heavy paper used, for the attractive maroon-colored gold-stamped leather binding, and to the author for his careful, conservative and concise selection of material.

Odoratus Sexualis. By Dr. Iwan Bloch. A Scientific and Literary Study of Sexual Scents and Erotic Perfumes. Cloth. Price, \$5. Pp. 274. New York: American Anthropological Society, 1933.

Here is a reprint in English at a very high price of a rather obsolete essay on the relationship of odor to sex. It has long been understood that human beings possess odors which are quite distinctive and that perfumes of various types have been associated with sexual stimulation. The author discusses these matters from both ethnological and biologic points of view.

Código de deontología médica. Por Louis Alonso Muñozerro, presbítero, auditor fiscal del Supremo Tribunal de la Rota Española. Prólogo del Dr. A. Vallejo Nágera. Cloth. Pp. 250. Madrid: Ediciones Fax, 1934.

In this day of codes it is interesting to see what a really thoroughgoing code may be, for under this title, filling some 130 duodecimo pages, there is enunciated a code of medical ethics that leaves no aspect of the physician's life untouched. Three chapters are devoted respectively to the intellectual, moral and physical qualifications of the physician. His relationships to the sick, to society and to the profession are minutely analyzed. All matters pertaining to marriage, birth control, sterilization and artificial impregnation are treated from the strictly orthodox point of view, as might be expected. The author is a doctor of sacred theology and canon law; also a member of the Supreme Tribunal of the Spanish Rota.

One Hour of Medical History. Volume III. By Benjamin Spector, M.D., Director. Cloth. Price, \$2. Pp. 181, with illustrations. Boston: Tufts College Medical School, 1934.

The Tufts College Medical School has presented each year a pageant of the history of medicine. The first two have already been published in book form. With increasing experience the material becomes more finished. Students are chosen from the second, third and fourth years who make an earnest effort to bring to life the characters they impersonate. The present volume carries the reader and the listener from Imhotep to Roentgen. The book is nicely illustrated. The essays, while brief, are highly suggestive.

Anatomy of Animal Types for Students of Zoology. By E. A. Briggs, D.Sc., Assistant Professor of Zoology in the University of Sydney. Cloth. Price, 10/6. Pp. 250. Sydney, Australia: Angus & Robertson, Ltd., 1934.

Most of the textbooks about zoology are concerned with species not available in Australia. For this reason Prof. E. A. Briggs has prepared a manual of zoology especially for the Australian student, dealing with vertebrates and invertebrates that are used by the students in that country. His book will, of course, be useful to such students as a textbook and to those in other countries as a work of reference.

Biographical History of the Members of the McLean County Medical Society and Other Physicians Who Have Practiced Medicine in McLean County, 1854-1934. Paper. Pp. 79, with illustrations. Bloomington, Illinois: The Society, [n. d.].

On March 20, 1854, fourteen physicians assembled in Bloomington, Ill., to organize the McLean County Medical Society. On the fiftieth anniversary, in 1904, the society requested one of its charter members, Dr. C. R. Parke, then of Louisville, Ky., to write a history of the medical society to be included in a history then being prepared by the McLean County Historical Society. The brief history prepared by Dr. Parke is the opening chapter in this small volume. It is followed by the original constitution of the McLean County Medical Society and by the revised constitution, which went into effect Dec. 1, 1904. There is a list of all the presidents and secretaries and a brief bibliography of all the members from the organization of the society down to the present. The history closes with a brief account of several hospitals in Bloomington and of the eightieth anniversary and banquet of the McLean County Medical Society, held May 8, 1934.

Die Werke des Hippokrates: Die hippokratische Schriftensammlung in neuer deutscher Übersetzung. Herausgegeben von Dr. med. Richard Kasperer. Unter Mitwirkung von Prof. Dr. Georg Sticker, u. a. Tell 1: Sitten- und Ständelehre für Aerzte. Tell 2: Die Alt(bewährte) Heilkunst/Die Kunst. Die hippokratische Schriftensammlung in neuer deutscher Übersetzung. Boards. Price, 98.75 marks, per set. (Subskriptionspreis). Pp. 59; 59. Stuttgart & Leipzig: Hippokrates-Verlag G. m. b. H., 1934.

The author offers a new translation into German of the works of Hippocrates. It is to be published in parts with a hope of bringing physicians back to the hippocratic conception of diseases and its control.

Atlas of External Diseases of the Eye. By Humphrey Neame, F.R.C.S., Hon. Ophthalmic Surgeon, Royal London Ophthalmic Hospital. Cloth. Price, \$5. Pp. 110, with 51 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc. 1934.

This is an atlas containing fifty-one colored drawings of diseases of the lids and the eyeball. Accompanying each plate and opposite it is a brief discussion of the condition giving the signs, symptoms, diagnosis, etiology, pathology, prognosis and treatment of the conditions. Most of the plates are quite good and it is possible to make a diagnosis from the pictures alone. The book should be of value to the student and the general practitioner.

Les ordonnances du médecin praticien: 256 répertoires de thérapeutique clinique. Par MM. S. Abbateucci et al. Third edition. Paper. Price, 50 francs. Pp. 526. Paris: Masson & Cie, 1934.

This collection of highly practical brief articles on the non-surgical treatment of diseases, first suggested by Martinet, has been brought down to date in this revised edition by incorporation of recent progress. It is neither a treatise on therapeutics nor a mere formulary, but a collection of outlines of treatment

sketched by experts in their respective lines and made applicable to current clinical and social conditions. It is decidedly a book that the general practitioner who understands French would find a good investment.

Medicolegal

Medical Practice Acts: Injunction to Restrain Unlicensed Practice.—The state of Arizona, on the relation of the attorney general, filed a bill of complaint against A T Smith to enjoin him from practicing medicine and surgery without first having obtained a license to do so. The trial court sustained Smith's demurrer to the complaint and the state appealed to the Supreme Court of Arizona.

The complaint alleged that Smith was engaged in the practice of medicine and surgery without a license, that he was unskilful and uninformed in that practice, that he did not possess the moral and professional qualifications prescribed therefor, that his continuous and persistent practice constituted a public nuisance, detrimental to the public welfare and dangerous to the public health, and contrary to and against the public policy of the state. The regulation of the practice of medicine and surgery by the state has for its purpose, said the court, the protection of the public health, and the attorney general, as a legal adviser of the state, may properly institute and prosecute a suit against those who fail or refuse to comply with the requirements of the medical practice act.

When the defendant demurred to the complaint he admitted as true the facts pleaded therein. The difficult question in this case, said the Supreme Court, is whether, in the absence of specific statutory authority, a person may be enjoined from committing a crime for which the legislature has prescribed a punishment. The general rule is that the courts will not enjoin one from committing a crime. As an exception to this rule, however, it is generally held that an injunction will be granted to restrain acts constituting a public nuisance, if they affect the civil or property rights or privileges of the public, or affect the public health, whether such acts be denounced as crimes or not. Section 4693, Revised Code of Arizona, 1928, provides that "anything which is injurious to health is a public nuisance," and in the present case the state based its right to an injunction, in part, on the allegation that the acts of the defendant, because of his lack of training and education, constituted a public nuisance affecting the public health. It is obvious, observed the court, that one who knows little or nothing of the human body and its reactions is unable intelligently and wisely to diagnose or prognosticate human ills, or to adopt sanitary means to prevent their spread or to effect their cure. If in fact, continued the court, the defendant was unskilful and uninformed, as alleged in the complaint, and daily treated people for their ills, it was not only probable but very likely that he was injuring the health of those he treated rather than helping them. His acts were consequently injurious to health and a menace to life.

The court did not think, however, that the unlicensed practice of medicine and surgery was per se a nuisance, as seems to have been held in *Kentucky State Board of Dental Examiners v Payne*, 213 Ky 382, 281 S W 188, and in *State v Anderson*, 6 Tenn Civ App 1. In the opinion of the court, a license does not add to a person's qualifications. It only shows that the holder has complied with the law. His skill and ability as a practitioner would be the same before as after he secured the license. A person having a license from the proper authorities would be presumed to be qualified to practice, and, in a criminal prosecution for violating the law requiring a license before practicing, the absence of such a license would give rise to an un rebuttable presumption of disqualification. But, observed the court, in a proceeding for an injunction based on acts alleged to be injurious to health by reason of unskilfulness, ignorance and incompetence, the state must make out its case. In the present case, the complaint alleged that the acts of the defendant were injurious to health and constituted a public nuisance. These allegations were not only not denied but were admitted by the demurrer. The Supreme Court concluded therefore that the injunction should have been granted. The judgment of the

trial court was accordingly reversed and the cause remanded, with directions that a permanent injunction be issued restraining the defendant from the further practice of medicine and surgery without a license. Subsequently, however, on a rehearing of the appeal, the Supreme Court revised its order and directed the trial court to overrule Smith's demurrer and permit him to make further answer to the complaint—*State ex rel La Prade, Atty Gen, v Smith (Ariz)*, 29 P (2d) 718, 31 P (2d) 102.

Malpractice: Death Resulting from Chiropractic Treatment for Headache.—The defendant, a chiropractor, undertook to treat Mrs Thornton for a chronic headache by giving her so-called chiropractic adjustments daily. At the end of the fifth "adjustment" the patient complained of excruciating pains in her neck and head and the chiropractor called a non-sectarian practitioner. A blood vessel in the patient's brain seems to have been ruptured and the patient died about two weeks later. Attributing the death to malpractice on the part of the chiropractor, the plaintiff, her husband, sued the chiropractor. There was a judgment for the plaintiff and the chiropractor appealed to the Supreme Court of Florida.

For a plaintiff to recover in a malpractice suit, said the Supreme Court, he must show two things, namely, (1) that the defendant was unskilful or negligent and (2) that that want of care or skill resulted in injury to the plaintiff. The absence of either of these two conditions will defeat recovery. While an unfortunate result raises no presumption of negligent treatment, negligence may be inferred from circumstances. For the circumstances to raise a fair presumption of negligence, they must of necessity not only be consistent with the theory that the injury resulted from negligence but also be inconsistent with the theory that the injury resulted from any other cause which might just as reasonably and logically be established by the circumstances. Applying these general principles to the facts of this case, the court said:

The jury in the case decided that the treatment administered by the doctor [chiropractor] produced the patient's death, which was caused by a ruptured blood vessel in the brain. This conclusion was evidently arrived at from the evidence of physicians and surgeons, who said that the rupture was caused by violence, and from the testimony of the defendant himself that the "adjustment" to which he submitted the patient, if properly made, could not have caused the rupture. That the rupture was caused by the adjustment was evidenced by the fact that the patient went to the doctor's [chiropractor's] rooms for a treatment like that which she had before received, and, while under the treatment, suddenly suffered the shock which resulted in severe pain and subsequent unconsciousness.

The Supreme Court accordingly affirmed the judgment in favor of the plaintiff—*Foster v Thornton (Fla)*, 152 So 667.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Recurrences in Pneumococcal Pneumonia.—Finland and Winkler present a study of fifty-seven cases of recurrent attacks of pneumonia associated in each instance with serologically identified pneumococci. An analysis of the major features of the early attacks and of the recurrence fails to indicate any marked change in the local or type specific susceptibility. The distribution of types of pneumococci and of the sites of the pulmonary lesion, in both the early and the late attacks, was similar to that usually observed in pneumococcal pneumonia. A larger number of cases had more extensive and "atypical" lesions during the recurrent attack. Specific serum therapy in the first attack in general had no marked effect on the character of the recurrence. Early recurrences with the same type, however, are more frequent among the cases treated with serum.

Cytology of Pleural Effusions in Pneumonia.—Scott and Finland used the supravital technic described by Forkner (a modification of the methods of Simpson and Sabin and their associates) to study the cytology of fifty-three pleural fluids obtained from thirty-two patients having pneumococcal lobar pneumonia. The cellular content of the infected fluids consisted almost exclusively of polymorphonuclear neutrophils in various stages of degeneration. In uninfected fluids the predominating cells, in the beginning, were active polymorphonuclear neutrophils, but these decreased in number during the first week, at which time monocytes and macrophages appeared in the fluid. Later in the disease, after crisis had taken place, lymphocytes began to appear in these sterile fluids. Moderate to marked eosinophilia was noted in three cases.

This occurred during the third week or later after the onset of the pneumonia.

Enlargement of Heart Due to Abnormal Glycogen Storage.—Antopol and his co-workers report a case of glycogenesis confirmed by necropsy. They state that deposits of glycogen may occur in the liver, kidneys, brain, heart, blood vessels, muscles and organs of internal secretion. The clinical picture depends on the sites of deposition and on the extent to which the vital processes of the affected tissues are interfered with. So far three main symptom groups are known, due to preponderance in the liver and the kidneys, in the heart and the blood vessels or in the brain. The first is the best known and possibly the largest group—the hepatonephromegaly glycogenica of von Gierke. The second group—that with cardiac hypertrophy—gives a clinical picture which, in the absence of proper chemical and histologic studies, may be confounded with the so-called idiopathic hypertrophy of the heart, as pointed out by Pompe. It is possible that many of the cases formerly classified as idiopathic hypertrophy belong to the von Gierke type of disease with enlarged heart and that rhabdomyomas are localized collections of fibers rich in glycogen, due possibly to focal disturbance in the metabolism of glycogen. In many cases of the so-called idiopathic hypertrophy vacuoles have been noted in the cardiac muscle but were not explained, and their association with large livers and enlarged kidneys is frequent. The third group, i. e., with cerebral symptoms due to glycogen deposits in the brain and spinal cord (Kimmelstiel) makes necessary a review of all poorly understood cerebral conditions in children in order to determine whether some of them are not related to the effect of abnormal glycogen storage.

Auricular Fibrillation After Goiter Operations.—According to Ernstone and Mulvey, sixteen (7 per cent) of 213 patients having hyperthyroidism had auricular fibrillation during the preoperative period, while postoperative auricular fibrillation developed in thirty-one (16 per cent) of the 197 who had normal rhythm before operation. The arrhythmia was present before operation in two of 192 patients who had adenomatous goiter without hyperthyroidism and developed after operation in four. The age of the patient, type of goiter and duration of hyperthyroidism appear to be the most important factors predisposing to the development of postoperative auricular fibrillation. The degree of elevation of the basal metabolic rate is of little significance. The immediate increase in the rate of metabolism following operation probably is the essential factor responsible for the initiation of the arrhythmia. Postoperative auricular fibrillation is more common in thyrotoxic patients having an adenomatous goiter than in those with hyperplastic goiter. This difference cannot be explained entirely by differences in the ages of the patients belonging to the two groups. The long duration of thyroid enlargement in the majority of patients having adenomatous goiter may favor the gradual development of myocardial damage, possibly as the result of repeated or prolonged periods of low grade, unrecognized hyperthyroidism. Postoperative auricular fibrillation generally begins during the first sixty hours after operation. It rarely causes circulatory embarrassment, and normal rhythm is reestablished spontaneously within forty-eight hours.

Tonsillectomy in Tuberculous Adults.—Newhart and his associates found that the incidence of tuberculosis of the tonsils in 112 tuberculous adults was 42 per cent. If the twelve cases without pulmonary tuberculosis were eliminated, the incidence would increase to 48 per cent. Serial sections of the excised tonsils would materially increase the incidence. This was demonstrated by a study of twenty pairs of tonsils, in four of which tuberculosis was found. These had previously been reported negative by the usual microscopic study. In a control series of 100 routine tonsillectomies, the incidence was 1 per cent, the positive case being found in a patient who had previously been treated for active pulmonary tuberculosis. Tuberculosis of the tonsil is a "latent" lesion, in that there is rarely enough destruction of the tonsillar substance to cause "gross" or ulcerative lesions. The tubercles in the tonsil are

usually in close proximity to the cryptal epithelium. The tubercles are primarily epithelioid in type, with giant cells nearly always present. Caseation is found in about half the cases and is not marked. The tonsils, in the authors' opinion, become infected by tubercle-laden sputum secondary to the open tuberculous pulmonary lesion. No case of primary tonsillar tuberculosis could be demonstrated in their series. Tonsillectomy in the tuberculous, when the patients are carefully selected and prepared, safeguarded by a proper operative technique and given the postoperative care demanded by their condition, presents no special hazard that would justify failure to perform tonsillectomy when indicated.

Etiologic Factors in Formation of Cholesteatoma.—Day believes that the primary and major factor in the development and growth of cholesteatoma is the presence of moisture. The surface epithelium of the body does not tolerate moisture well, and the continued contact of moisture causes irritation and desquamation of epithelium. The squamous stratified epithelium, which grows into the tympanic cavity and gives rise to cholesteatoma, is surface epithelium. The desquamation of epithelium and formation of cholesteatoma are primarily due to the constant presence of moisture bathing the epithelium. The author states that only anhydrous solutions should be employed in the presence of cholesteatoma. Conservative treatment should be tried only in the absence of symptoms or signs of extension beyond the confines of the middle ear and mastoid. Cures can be obtained only if there is complete epidermization of the walls of the cavities. The presence of moisture will prevent cures and cause recurrences. This is especially true if there are granulations or if an open eustachian tube is present. Conservative treatment is rarely successful in young children because of tubal secretion. The early recognition and proper treatment of chronic otitic suppuration with cholesteatoma should obviate the need of radical surgery and prevent the serious complications that occur so commonly at present.

Cutaneous Rheumatic Nodules.—Rosenberg presents two cases of cutaneous rheumatic nodules with biopsies that occurred in adults. Histologic examination of a biopsy specimen of one of the cases showed that the epidermis was slightly thickened and the layer of keratohyalin well developed. Between the prickle cells were single cells, which were swollen with clear cytoplasm and pyknotic nuclei. The papillary layer of the cutis appeared loosened; the lymph vessels were dilated and the fibrocytes were swollen. There was slight acanthosis, and at the height of the tips of the rete pegs the cutis showed loose accumulations of small round cells, histiocytes and occasional plasma cells, which centered about capillaries with swollen endothelial cells. In the reticular layer of the cutis the edema and the perivascular infiltration were more marked, and the connective tissue trabeculae were often separated by rows of round cells which radiated from the cellular adventitia of the capillaries and the precapillary and postcapillary blood vessels. These vessels showed a slight thickening of the wall caused by a swelling and increase in the number of endothelial cells. The adventitial cells were swollen and more numerous than normal. There were similar infiltrations about the sweat

glands, which, however, were less marked than those about the blood vessels. In the subcutaneous fat tissue corresponding to the center of the infiltrated area was a small artery, the endothelial cells of which were so swollen that they resembled the epithelial lining of a gland. Sheets of desquamated endothelial cells with fibrin, leukocytes and round cells filled the lumen. The media stained pale, the muscle fibers were poorly differentiated and the nuclei were shrunken; the adventitia contained round cells and leukocytes, and similar cells were found between the adjacent fat cells. The small cutaneous nerves were surrounded by several rows of lymphocytes.

Fungi of Blastomycosis and Coccidioid Granuloma.—Benham describes three types of mycotic infection—cryptococcosis, blastomycosis and coccidioid granuloma. Each is a distinct disease etiologically. The infections may be diagnosed by the characteristic picture of the fungus in the lesions and this diagnosis may be confirmed by culture. The differential characteristics of the three fungi—*Cryptococcus hominis*, *Blastomyces dermatitidis* and *Coccidioides immitis*—are given for the sake of clearness. The author states that in addition to these three fungi there are at least seven others that may cause systemic infections with granulomatous lesions and appear in the infected tissue as rounded cells more or less resembling yeasts. *Torula histolytica*, *Glenospora gammeli*, *Monosporium tulaneense*, *Endomyces capsulatus*, *Geotrichum* (*Blastomycoides*) *dermatitidis*, *Scopulariopsis americana* and probably other strains reported under various names seem indistinguishable from one or another of the three types described. For the recognition and identification of these fungi it is necessary to observe their morphologic characteristics both in the tissue of the host and in culture, their cultural characteristics, and, in the case of the first type, their serologic reactions.

Operation to Control Glaucoma.—After testing experimentally the possibility of establishing a fistulous tract from the anterior chamber through the suprachoroidal space and out through the sclera, for the control of intra-ocular hypertension, Row performed the horsehair insertion operation in a case of glaucoma secondary to the extraction of a cataract, in which the iris had become incarcerated in the incision, and in a case of bilateral absolute glaucoma, with constant and severe temporal headache. In this case both eyes had been operated on, the right eye once, by cyclodialysis, and the left eye twice, first by cyclodialysis, followed later by Elliot's operation, in an attempt to reduce the tension and thereby relieve the headache. Insertion of the horsehair was possible only after introducing a grooved spatula in the cyclodialysis tract. For this purpose a Knapp iris repositr was used, which acted as a guide to the hair as it was fed into the groove with a pair of tissue forceps. The possibility that sympathetic ophthalmia might be induced by this operation must not be overlooked. The fact that the operation opens a natural line of cleavage between the sclerotic and the choroid makes it incomparable to the violent, lacerating type of injury, perforating usually all three coats of the eye, which so frequently precedes the establishment of sympathetic ophthalmia. The author recommends

a trial of the horsehair inclusion procedure in cases of primary bilateral absolute glaucoma. To his knowledge there is no other nonmutilating operation that offers any degree of success in such cases. Disregarding the consideration of sympathetic ophthalmia and assuming that by this procedure a sinus tract is opened from the anterior chamber back through the supra-choroidal space and thence into the deep orbital tissues, well covered and protected by Tenon's capsule, the possibility of late infection, as in other operations establishing a fistulous tract, is practically eliminated.

Carcinoma of Maxillary Sinus Extending into Cranial Cavity.—Finkelman and Wick report a case of a transitional cell carcinoma of the maxillary sinus extending into the cranial cavity. The development of the signs and symptoms in this case was at first due to the tumor near its origin. Later, with extension of the tumor into the cranial cavity, the patient complained of failing vision (optic atrophy and choked disk). The mental symptoms were probably a result of increased intracranial pressure. Neuropathologic examination of the brain and eye revealed arteriosclerotic changes in the brain, optic atrophy and disappearance of the ganglion cell layer of the retina.

The Synovial Fluid in Gonococcal Arthritis.—In studying the synovial fluids from forty cases of gonococcal arthritis, Myers and his associates found that: 1. When the joints became involved as a result of a gonococcal infection, the synovial fluid was either infected or noninfected. In either case the fluid had the characteristics of an exudate as judged by both the total protein and cell content. 2. The total synovial fluid cell count was increased in both types of fluid, but, as a rule, it was somewhat higher in the infected fluids. There were, however, wide variations. 3. The differential cell count was of greater importance than the total cell count in the two groups of cases. In practically all, the polymorphonuclear cells predominated. In the noninfected fluids, the clasmatocytes, monocytes and lymphocytes were present in much larger numbers than in the infected fluids. 4. The nonprotein nitrogen content of the synovial fluid was the same as that of the blood regardless of the presence of organisms or of a high cell count. 5. The sugar content of the synovial fluid varied with the level of the blood sugar, the number of leukocytes and the presence of bacteria. Of these factors the first two were of greater importance than the third. 6. The results of gonococcus complement fixation tests on the synovial fluid and blood were in agreement. 7. The bacteriologic, cytologic and serologic tests were of the greatest value in providing information of diagnostic value. 8. The chemical examination of the fluid revealed no information of diagnostic importance. 9. While the prognosis, as far as complete recovery was concerned, was poor, the presence of micro-organisms and a high leukocyte count were more often followed by chronic disease of the joints than when there was a low leukocyte count and a sterile fluid.

Treatment of Pellagra.—Spies used autoclaved yeast, desiccated hog stomach and parenteral liver extract in the treatment of pellagra. When the patient's diet was restricted to large amounts of either autoclaved yeast or desiccated hog stomach, the oral lesions of pellagra healed rapidly. This suggests that there may be some etiologic relationship between pellagra and pernicious anemia. The evidence is too meager at the present time to justify the designation of vitamin G as the specific substance capable of curing pellagra. The oral manifestations of sixteen pellagra patients responded dramatically following the parenteral administration of massive doses of liver extract. The author suggests the use of large doses of liver extract, either intravenously or intramuscularly, whenever a patient severely affected has difficulty in ingesting or assimilating sufficient quantities of a highly nutritious diet.

- Physical Dynamics of Encephalography. P. G. Schube, Boston.—p. 291.

Acute Aseptic Meningitis.—Patients having acute aseptic meningitis, described by Viets and Watts in 1929, have been reexamined and found to conform with Wallgren's description. Contrary to their opinion expressed in 1929, they now believe that the changes in the cerebrospinal fluid are not exclusively lymphocytic, although essentially so. Clots, also, may be found in the fluid. The most important point in differential diagnosis between this disease and tuberculous meningitis is the constantly normal sugar and chloride content of the cerebrospinal fluid in acute aseptic meningitis, contrary to the observations in tuberculosis. The disease should be considered a clinical entity, because no definite relationship has been shown to exist between it and any other diseases.

Treatment of Muscular Dystrophy with Gelatin.—Stone and Abeles used sheet gelatin in treating fifteen cases of muscular dystrophy and other similar disorders, as it is cheap and contains from 15 to 20 per cent of glycine. The gelatin, 100 Gm., was emulsified in orange or pineapple juice and given to the patient as a daily ration, to be taken at his convenience during twenty-four hours. The cases treated were of long standing, probably much less amenable to any form of therapy than incipient cases. Nine exhibited subjective sensory phenomena. Of these, five showed muscular dystrophy, one myasthenia gravis, one amyotrophic lateral sclerosis(?), one progressive muscular atrophy(?) and one chronic anterior poliomyelitis. Nine patients felt subjectively stronger to varying degrees. Eight showed an increase in muscular strength, omitting the myasthenic patient, who may have had a spontaneous remission. The changes varied in degree: they were all slight and two were altogether questionable. One myasthenic patient continued a downward course begun previously. Of the patients who improved objectively, five had muscular dystrophy, one had amyotrophic lateral sclerosis, one had progressive muscular atrophy(?) and one had chronic anterior poliomyelitis. The patient with amyotrophic lateral sclerosis (an advanced case) died six weeks after the discontinuance of treatment, his death being probably of bulbar origin. The authors believe the clinical phenomena sufficient to indicate that the substance has some therapeutic potency, which is possibly more marked in incipient cases. The therapeutic effect is probably due to the glycine content. The gelatin is bulky and unpalatable, and the results do not indicate superiority over pure glycine. Nevertheless, it might be the subject of further experiment in an effort to provide an inexpensive source of glycine. Beyond gastric discomfort and muscular dysesthesia there were no ill effects that could be attributed to the gelatin. The presence of sensory phenomena and even slight motor improvement in cases other than primary muscular dystrophy suggests that there may be similarities, perhaps identities, between the primary disorders of muscle metabolism and those of neurogenic origin, and that some aspects of the latter disorders may therefore be influenced favorably by glycine.

Postmortem Roentgenograms.—Bowen points out that the postmortem roentgenogram is of great assistance when necropsy is not possible or desirable. In accident cases it will often reveal the cause of death and the extent of the injury. In cases of sudden death with thoracic symptoms it is often revealing, and in ordinary fatal medical and surgical cases it will demonstrate the terminal condition and give additional information as to the cause of death. In terminal accidents, such as spontaneous pneumothorax, hemorrhage from the heart, the lung or an aneurysm, pulmonary embolism or infarct, massive atelectasis or acute dilatation, a postmortem roentgenogram will show the condition. In a certain number of cases it will reveal as much as a necropsy examination and may be substituted for one. When late antemortem roentgenograms have been secured, they of course serve the same intent and purposes as the postmortem roentgenogram. Postmortem roentgenograms offer an important and instructive instrument for adding to the knowledge of the clinician, pathologist and roentgenologist.

Congenital Absence of Abdominal Muscles.—Housden reports a case of congenital absence of the abdominal muscles, presents the salient points of the thirty-three cases recorded previously and discusses the various views on the etiology of the condition. From this review he believes that the absence of the abdominal muscles is due to the atrophy of muscles formed previously, by pressure from an enormously dilated bladder and ureters, such pressure being probably increased by secondary ascites. The cause of the dilatation and hypertrophy of the bladder is considered to be an organic obstruction in the urethra, due no doubt to a neuromuscular incoordination (an achalasia of the vesico-urethral orifice) or to a definite organic obstruction.

Acid Metabolism in Rheumatic Children.—In an effort to determine whether there was a difference in the acid-base balance of the blood in the normal and the rheumatic child, Payne examined the urinary output of 200 rheumatic, asthmatic and normal children, respectively. The asthmatic group was chosen because at the time it was postulated that an element of alkalosis entered into the asthmatic syndrome. The observations show that the rheumatic child in a quiescent interval excretes more acid in its urine than does either an asthmatic or a normal child. Part of this excess of acid is due to organic acids. This excess production of acid is insufficient to disturb the equilibrium of the blood.

Parasympathetic Nerve Supply to Distal Colon.—Trumble agrees with Telford and Stopford that nerve bundles do ascend in the hypogastric nerves from the pelvic nerves, but he maintains that these nerves do not represent the sole or main pathway for fibers of the pelvic nerves passing to the distal colon (excluding the rectum) and are merely the uppermost (probably) of a series of nerves supplying the intestine segmentally. They may be called the pelvic colonic nerves. The ascending pelvic colonic nerves do not enter the sympathetic perivascular plexuses, as a rule, but pass across these and enter the mesenteric border of the intestine direct and not in company with the vessels entering the intestine. They do, however, communicate with the perivascular plexuses. Often the uppermost nerves from the two sides do not unite but pass, one on each side of the inferior mesenteric artery and nerve plexus, to reach the colon.

*Urinary Elimination of Chlorides in Bullous and Vesicular Disorders of Skin. R. Zorn and P. Popchrisstoff.—p. 667.

Anticerebral Reagin in Cerebrospinal Fluid.—Demanche has made more than 1,000 comparative fixation reactions with an extract of brain and an extract of cardiac muscle, both on the cerebrospinal fluid and on the serum of patients suffering from various diseases. The myocardial antigen was an alcoholic extract of powdered heart previously extracted with ether and with 0.3 per cent cholesterol added. The cerebral antigen was an extract of human cerebral gray matter treated in the fresh pulp state without preliminary ether extraction in order to preserve the cerebral lipoids. The dry extract of both was 10.5 Gm. per liter. Their cholesterol content was 3.52 Gm. per liter for the cerebral extract and 4.16 Gm. per liter for the heart. The addition of cholesterol largely compensated the latter for the natural abundance of cholesterol in the nervous tissue. It was determined that the antigen had no anticomplementary power and that a similar testing of complement was applicable for both. The technic of the reactions was that of the author's modification of the Wassermann test. In order to study the results, the patients were divided into five groups: dementia paralytica, tabes, cerebrospinal syphilis comprising the different forms of secondary or tertiary meningo-encephalitis, nonsyphilitic disorders of the central nervous system, and generalized syphilis of different stages without characteristic nervous lesions. Analysis of the results indicated that the cerebrospinal fluid of patients having dementia paralytica and tabes possesses almost exclusively a special property of reacting in vitro with cerebral extracts. This reactivity is absent in all the other fluids and usually in the blood serum. Thus the group of parasyphilosis differs from other forms of nervous syphilis, and generally the cerebrospinal fluid from the blood serum. The author believes that the existence of these special anticerebral reagins confirms the doctrine of the local origin of the cerebrospinal reagins and brings a new argument in favor of the antigenic power of the organic lipoids and of the specificity of the cerebral lipoids. It also furnishes a supplementary procedure for the biologic diagnosis of parasyphilosis.

Elimination of Chlorides in Disorders of Skin.—Zorn and Popchrisstoff investigated the chloride metabolism in a number of patients with bullous and vesicular skin conditions. The amount of chloride usually ingested was 6.5 Gm. a day, though sometimes a diet containing from 10 to 12 Gm. was used. In every case it was felt that the chloride intake could be estimated within 0.5 Gm. limits. The method of Charpentier-Volhardt was used for determining the amount of chlorides in the urine. The results obtained from all patients in whom any doubt existed as to chloride intake, completeness of urine collections or other factors were discarded. In the one case of pemphigus satisfactorily studied there was a considerable chloride retention. They did not feel, however, that this was a cardinal etiologic phenomenon. In papulovesicular eczema an important chloride retention was observed in the majority of cases. By following these patients from day to day it seemed that this retention was accompanied by a juiciness of the affected cutaneous regions. They believe that the retained chlorides serve to form edema and the histologic sponginess that signifies eczema. In these cases of eczema in which it is not proper to speak of renal lesions, the formation of the edema practically coincides with the reestablishment of the elimination of chloride.

- *Value of Vernes Test: Relation to Fixation of Complement Tests of Matefy, Daranyi and Fahreus. F. Díez Melchor.—p. 265.
Interlobular Pleurisy Opened into Bronchus: Case. L. Eizaguirre.—p. 276.

The Vernes Test.—Díez Melchor concludes that the fixation of the complement and the flocculation tests are the biologic methods most frequently resorted to for the diagnosis of the various forms of tuberculosis. The Vernes test is not specific, because it gives positive results in syphilis and in infections, and it gave negative results to the author in 16.94 per cent of the cases of proved tuberculosis. It has no diagnostic value.

The diagnosis of absence of tuberculosis based on the negative results of the test is more exact than that of its presence based on its positive results. The Vernes test has no relation to the anatomoclinical form of tuberculosis or to the extension of the lesions, but only to the degree of activity of the lesions. Hence its prognostic value. The highest figures of positive results of the test are given by the caseous and fibrocaceous forms in their period of evolution. The lowest figures of positive results and the large percentage of negative results of the test are given by the fibrous forms. The fixation of the complement is the only specific test for the diagnosis of tuberculosis. The results of the other reactions studied by the author (Matefy, Daranyi and Fahreus tests) were similar to those given by the Vernes test. These reactions are of physical nature showing only the presence of colloidal instability of the serum. The results of the Matefy and Daranyi tests absolutely lack diagnostic and prognostic value. The velocity of the sedimentation bears a close prognostic relation to the Vernes sero-reaction.

 *Special Position of Tubular Ovarian Blastomas (Arrhenoblastomas) as Regards Morphology and Hormone Function. H. O. Kleine.—p. 410.

Uterovaginal Tamponade in Atonic Hemorrhages of Uterus.—Kiss reports the experiences with Dührssen's uterovaginal tamponade in Hungary during the years 1931 and 1932. His report is based on 149 cases. This number amounts to 0.24 per cent of the total number of births. In general practice the method was resorted to in 0.03 per cent of the cases. The tamponade was nearly always made in the uterus and the vagina; once it was made only in the uterus and twice only in the vagina. In deciding on the tamponade, it was less the quantity of blood lost but rather the condition of the woman that was the determining factor. Tamponade was resorted to immediately in the clinics in only 5.7 per cent of the cases; in all other cases, less radical methods of hemostasis had been tried first; in private practice, tamponade was done at once in 28.08 per cent of the cases. The higher incidence of primary tamponade in the latter cases was due to the fact that there was no time left for trials with less radical methods. As to inspection of the uterus and removal of retained membranes, the author is of the opinion that it is advisable in institutions, where the intervention can be made with complete asepsis. Hemorrhages following placenta praevia were treated with tamponade in only 4 per cent of the cases. The mortality rate due to fatal hemorrhage amounted to 12.2 per cent in the material studied by the author. The danger of infection often credited to uterovaginal tamponade should be ascribed to previous intra-uterine interventions.

Special Position of Arrhenoblastomas.—Kleine points out that thirty-five cases of arrhenoblastomas of tubular structure have been reported thus far. Among the four cases that he observed was one in which there were dermoid cystomas in the other ovary. The growth of these tumors had begun at the hilus. Leydig's interstitial cells were demonstrable in all tumors. All patients exhibited more or less characteristic signs of virilism (psychic changes, altered body contours and changes in the hair growth and in the voice). In one patient the rete ovarii of the other ovary was considerably enlarged but was free from tumor cells. The development of a post-operative hyperthyroidism in one of the patients indicates the possibility of a pluriglandular disturbance. Reasoning along the lines suggested by R. Meyer, the author thinks that the parent tissues of the arrhenoblastomas are the rete ovarii, the medullary strands and the so-called extraglandular interstitial cells. These three epithelial formations represent-heterosexual cell complexes of the ovary, which are present in small amounts in every

ovary. The hypoplasia of the isosexual gonadal parenchyma seems to promote the development of the heterosexual tissues. The observations of other authors (R. Meyer) on younger women with arrhenoblastoma, in whom signs of virilism appeared simultaneously with the growth of the tumor, disappeared after extirpation and reappeared in case of relapse, prove a causal, incretory connection between these tumors and virilism. The author shows that three problems have yet to be solved: (1) the significance of the rete testis and of Leydig's interstitial cells for the development of the secondary male sex characters, (2) the problem whether arrhenoblastomas form a testicular incretion, and (3) whether there are relations between arrhenoblastomas and the suprarenal system.

Progressive Muscular Dystrophy: Heredity and Treatment with Glycine.—Kostakow publishes a genealogical table with fifty-five members in three generations which reveals that fifteen of the descendants developed progressive muscular dystrophy and that all fifteen were boys. The girls remained healthy but transferred the disease to their sons. The six daughters of the first generation passed the disorder on to one or two of their sons, in all to 88 per cent of the males of the second generation. Seven women of the second generation, although themselves free from the disease, passed it on to six out of eight boys of the third generation. The children of the men, who had remained free from the disease, remained free from it through three generations. Thus progressive muscular dystrophy has a mode of heredity, in which the women transmit the disease although they themselves remain free from its symptoms; that is, the heredity is sex limited and recessive. A study of the cases of the successive generations revealed homology and homochronicity but no progressivity. The author discusses the value of glycine in the treatment of progressive muscular dystrophy. His observations were made in sixteen cases (fourteen from the genealogical table and two others). A tabular report of the results of the treatment indicates that the degree of improvement and the responsiveness of the disorder are dependent on the length and the progressiveness of the disorder but not on the age of the patient. The author gained the impression that the degree of improvement is proportional to the extent to which the muscles are still capable of reacting and inversely proportional to the progressiveness and the duration of the disorder. He rejects the statement that children with progressive muscular dystrophy are not at all or only slightly influenced by glycine, for his observations on seven children who improved greatly disprove this. He admits, however, that glycine is ineffective in cases with myasthenic components or with degenerative atrophies in syringomyelia, in spinal forms and in bulbar paralysis. Glycine treatment is indicated in pure myopathy and, to a certain extent, in cases in which on the basis of the clinical and electrical behavior serious impairment of the peripheral neuron can be excluded. He emphasizes that active patients require much larger quantities of glycine than do patients who rest.

Localization of Cardiac Infarct by Means of Electrocardiogram.—Katz points out that studies by Herrick, Smith, Pardee and others have made an electrocardiographic diagnosis of cardiac infarct possible. According to whether the characteristic sign, the reversion of the T wave, is found in the first

or in the third lead, Parkinson and Bedford differentiated two types of changes, T_1 and T_2 . Later it was proved by Barnes and Whitten that this differentiation is of practical significance in that it permits an exact localization of the cardiac infarct. If the left coronary artery is occluded, the infarct is, as a rule, in the region of the apex of the heart, in the anterior wall of the left ventricle and in the anterior portion of the ventricular septum. The electrocardiogram reveals in these cases a reversion of the T wave in the first lead (type T_1). However, if a branch of the right coronary artery is obstructed, an infarct is nearly always in the posterior wall of the left ventricle and in the posterior third of the ventricular septum, and the electrocardiogram shows the characteristic changes, particularly the deep and pointed T wave in the second and third leads (type T_2). These observations have been corroborated by several investigators. The author observed in recent months two cases in which the localization that had been based on electrocardiography was corroborated by the necropsy. She gives detailed descriptions of these cases. One of them is especially noteworthy because the right ventricle was involved in the infarct formation, and this is rather a rare occurrence.

Ammonia Content of Blood in Estimation of Liver Diseases.—Monguió and Krause say that ammonia is produced in various functions of the organism. They give their attention mainly to the ammonia that is formed in the intestine and in the intermediate metabolism and enters the blood and then the liver, where the ammonium salts are changed into urea. Urea formation from the ammonium salts is one of the most important functions of the liver, for it prevents a sudden flooding of the organism with intoxicating ammonium ions. The amount of ammonium ions in the blood and in the tissue fluids must therefore present an indicator for the capacity of the liver to form urea. The authors found that the normal value of blood ammonia in human subjects varies between 0.028 and 0.06 mg. per hundred cubic centimeters of blood. They report their studies on normal dogs, on dogs with ligated choledochus and on dogs with Eck's fistula. They believe that their studies brought the experimental proof of Thannhauser's theory, who, like Fischler, considered poisoning due to the consumption of large amounts of meat an alkalotic condition produced by a flooding of the organism with ammonium ions. The aspects of chronic meat poisoning that developed in the dog with Eck's fistula, as well as the symptoms that developed after administration of urea and urease, justify the conclusion that a hyperammonemia is the cause of the vomiting and of the soporose state. For clinical and dietary procedures, these studies are important in that they indicate that in disturbances in which the parenchyma of the liver is impaired the protein intake should be curtailed as much as possible, while the carbohydrate intake is increased. Thus a method of treatment, which formerly had been adopted more or less intuitively, has now been given an experimental foundation.

Stability of Ergot Preparations.—Rothlin demonstrates that the stability of ergot preparations is rather limited. He sees the cause of this in the high sensitivity of the specifically active ergot alkaloids to air, light, alkaline reaction and high temperature. But in addition to these there must be still other as yet unknown factors, for even extracts that have been prepared and stored in the same manner show a different rapidity of disintegration. Tests revealed that even some of the pure extracts of ergot alkaloids have an insufficient stability. Ergotamine tartrate, however, was an exception, for it proved stable in controls extending over a period of twelve years. The histamine contained in ergot extract was found to disintegrate almost as rapidly as the alkaloids.

Roentgenologic Demonstration of Subnormal Length of Leg.—Bamberger and Zeitter point out that a difference in the length of the two legs is frequently the cause of an abnormal position of the pelvis and of the development of scoliosis. An exact determination of the difference in length is therefore highly important in orthopedic prophylaxis. The methods so far available lacked in exactness because it is difficult to feel through the skin the measuring points on the skeleton, and also because asymmetrical posture and restlessness on the part of the patient falsified the results. This induced the authors to devise a new method, which employs two wooden bars, one meter in length and marked with millimeter graduations. Each of these bars has two metal sliding pieces. The slides have a clamp that serves for the attachment of the roentgen cassette and a securely fastened small metal indicator that projects from 3 to 4 cm. at a right angle over the edge of the measuring bars. The two bars are placed parallel on the roentgen table and to each slide is fastened a roentgen cassette (9:12 cm.). The indicators should be approximately in the middle of the long side of the cassette. The patient is placed in such a manner that the hip joints are above the middle of the upper cassettes and the ankle joints on the two lower ones. It is advisable to make the distances of the slides the same on the two bars, since this prevents mistakes and also unnecessary calculations. The roentgen tube is at a distance of 1.5 meters and approximately above the knee joints. The four joints and the four slide indicators are photographed at one exposure, and the distance between the articular spaces (or other points on the femur or tibia) and their respective metal indicators are measured on the photographs. The sum of these distances left and right, respectively, reveals the difference in the length of the two extremities.

Histamine-Like Action of Substance in Tomatoes.—The observation of certain circulatory manifestations in patients receiving a diet with large amounts of vegetable juices induced Gleichmann to search for substances with circulatory action in various vegetables. Traces of such substances were detected in carrots, potatoes and cabbage, but tomatoes contained substances with circulatory and secretory action in unusually high concentration. The author relates extensive experiments, which prove that tomatoes, ripe as well as green and fresh as well as canned, contain substances of intense biologic action. These substances are filtrable through a Berkefeld filter, have a high degree of thermostability and are resistant against digestion with hydrochloric acid pepsin. They have a tonicizing effect on the intestine, uterus, gallbladder and gastric muscles of guinea-pigs. Tests on dogs revealed that the biologically active substances contained in tomatoes promote the secretory action of the stomach by increasing the quantity as well as the acidity of the gastric juice. The substances increase also the secretion of pancreatic juice, but their effect on the secretion of bile is not quite clear. They produce a temporary reduction in blood pressure in atropinized as well as nonatropinized cats and rabbits. The diuresis is slightly increased by the tomato extract. Other problems, such as the decrease in blood pressure following intake of large amounts of the tomato extract into the gastro-intestinal tract, are still under investigation. Intracutaneous injections with the extract in human subjects reveals a tendency to wheal formation. The author is of the opinion that at least a part of the biologically active substances contained in tomatoes probably belong to the group of the histamine-like substances, but he considers it inadvisable to

identify them completely with histamine as long as the chemical proof has not been furnished. In a discussion of the clinical significance of the high content of tomatoes in histamine-like substances, he points out that the effects produced by diets providing large amounts of vegetable juices is probably largely due to their influence on the circulation, the vascular system and particularly the capillary apparatus. The efficacy of such diets in lupus, for instance, may be due to an improved blood perfusion. Moreover, the capillaries and precapillaries in a region of granulation and inflammation may be especially susceptible to small amounts of histamine-like substances. In this connection it is pointed out that under the influence of a vegetable diet abnormal capillary pictures frequently become more normal. The exclusion of the capillary obstructions effects an improvement in the regulation of the entire circulation, but particularly in the skin. This would also explain the efficacy of vegetable diets in capillomotor disturbances, hypertension, migraine-like conditions, angiospastic angina pectoris, Quincke's edema and eczemas and other skin disorders, which are caused by capillary disturbances.

Determination of Diameter of Erythrocytes by Diffraction.—Keller points out that, although the enlargement of the mean diameter of the erythrocytes has been known for a long time as one of the most characteristic and persisting symptoms of pernicious anemia, it was of little practical significance because of the lack of a simple method. This deficiency was overcome when Pijper rediscovered the diffraction method. The author reviews the principle of Pijper's method, mentions several other investigators who employed diffraction, and finally describes his own observations in experiments with Bock's simplified and improved apparatus. In order to determine the normal limits of the diameter of erythrocytes, he examined 1,158 specimens and found that the normal diameter varies between 7.30 and 7.76 microns. He considers 7.60 microns the normal mean. The diameter showed no differences in the two sexes. In twenty patients with pernicious anemia, eighty-six specimens were examined, and it was found that even in case of considerable remission the mean diameter never went below the upper limits of normality. The author emphasizes that diffraction is simpler than the determination of the color index, and also probably more reliable. It proved helpful in the determination of the efficacy of a treatment. Macrocytoses not caused by pernicious anemia were detected in twenty-five cases of tuberculosis. However, the erythrocytic diameter reached only in one case the extent it has in an untreated case of pernicious anemia, and it was always possible to differentiate these macrocytoses from pernicious anemia by other methods. In cases of secondary anemia the mean diameter was either normal or below normal. Leukocytosis up to 150,000 did not interfere with the diffraction method, but when the leukocytosis reached 400,000 it became impossible.

*Rheumatic Infection of the Kidney. V. G. Palilov.—p. 1031.

Treatment of Cerebrospinal Meningitis by Spinal Punctures and Insufflation of Air.—Matovetskiy reports the results obtained in fifteen cases of acute epidemic cerebrospinal meningitis treated by the method of repeated spinal punctures followed by insufflation of air. From 25 to 30 cc. of the cerebrospinal fluid is removed and with the aid of a sterile syringe utilizing the same needle, from 10 to 15 cc. of air is slowly introduced. This procedure is repeated after two or three minutes. In young children smaller amounts are removed and correspondingly smaller amounts of air are introduced. The puncture is repeated every other day, daily in severe cases, and is kept up until the fluid becomes clear and on examination shows a normal albumin content and normal morphologic elements. During the introduction of air, patients complain of a backache and a pain along the vertebral column. The headache becomes aggravated. This, however, is followed from

two to three hours later by a fall in temperature, remission of headache and an improvement in the general state. Of the fifteen patients thus treated, eleven got well and showed no sequels in a follow-up study from one to two years later. Of the four fatal cases, one was admitted with symptoms of vagus involvement, one exhibited a meningococcic bacteremia, two had a positive Queckenstedt sign, and the last exhibited xanthochromia of the spinal fluid. Results were always better when the treatment was instituted early. The author theorizes that the beneficial effect of insufflation of air is due to the washing out and forcing out of the infected fluid. The air, as it becomes warmer, rises into the subarachnoid space and displaces the fluid, which now may be removed by the secondary aspiration. The treatment may have the important effect of preventing formation of adhesions in the subarachnoid and spinal spaces. These adhesions may lead to a secondary hydrocephalus and to formation of encapsulated foci. The latter explain fatal exacerbations in apparently recovered patients.

Rheumatic Infection of the Kidney.—In histopathologic studies of seventy-five cases of rheumatic infection, Palilov found the existence of a diffuse glomerulonephritis in 16.2 per cent. He considers this alteration a specific manifestation of the rheumatic infection constituting, by its clinical course, a distinct cardiorenal type. Among rheumatic disorders of the kidney, the diffuse vascular alterations in the form of glomerulonephritis predominate over focal infections. The renal tissue is affected from the inception of the rheumatic process along with other organs and systems. The cardiorenal form occurs with greater frequency in older patients, those past 35, while the cardiac type without renal involvement is more frequent in younger patients. Renal involvement takes place in both the benign and the malignant types of rheumatic infection. It is apparently an identical process in the two. The course of the renal involvement is in most cases chronic, with a tendency to exacerbations in the form of acute glomerulonephritis. The chronic infection may be of a progressive character leading ultimately to renal insufficiency and uremic coma. Involvement of the kidneys aggravates the general course of the disease. The mortality in the author's material was 24.4 per cent during the first year for the cardiorenal type, as contrasted with 9.5 per cent for the cardiac type. The arterial blood pressure was found to be higher than in the cardiac form, but seldom as high as in nonrheumatic renal disease. The characteristic tendency to hypotonia is likewise manifested in the cardiorenal form of the rheumatic infection.

*Cytologic Review of Different Forms of Goiter, Compared with Clinical Cases. S. Franck.—p. 327.

Cytologic Review of Goiter.—Franck tabulates ninety-eight cases, consisting of forty-nine of exophthalmic goiter (thirty-three with preoperative iodine treatment), five of toxic and forty-four of simple colloid goiter, treated operatively from 1929 to 1931. In the cases of exophthalmic goiter there was constant marked enlargement of the Golgi apparatus, a phenomenon found only in milder degree in some instances of simple goiter. The possibility is suggested that anomalies in the relation between the thyroid gland and the pituitary body may be an important factor in the etiology of exophthalmic goiter.

A STUDY OF VACCINATION IN FIVE HUNDRED NEW-BORN INFANTS

H. H. DONNALLY, M.D.

AND

MARGARET M. NICHOLSON, M.D.

WASHINGTON, D. C.

More interest in early vaccination of infants has developed in recent years than ever before because of more concern for public health and preventive medicine, and the desirability of having as many as possible in the general population immune to the various preventable diseases. For the most part compulsory vaccination in the United States applies only to children before they enter the public schools. This allows vaccination in the majority of children to be deferred until school age, whereas it has long been established, although not so widely carried out, that infants, even new-born infants, bear vaccinia well, with a moderate local and insignificant constitutional disturbance, such as a febrile reaction, an altered well being and an unfavorable effect on nutrition. Statistical tabulations¹ of vaccinal encephalomyelitis are uniform in disclosing that its occurrence is lowest among infants vaccinated in the early months of life. This fact has undoubtedly stimulated interest in early vaccination.

HISTORICAL NOTES

Up to Jenner's time, smallpox was widely prevalent, devastating epidemics were frequent, and smallpox mortality was very high, especially among infants, in whom the disease exacted the highest toll. The method of prevention employed then was inoculation of matter from smallpox pustules into the skin of healthy subjects. The dangers of such a procedure² were very great and the outcome was uncertain, for smallpox generally resulted. If mild, the subject recovered with resulting immunity, but he first had smallpox none the less and was capable of and did at times actually spread smallpox to his contacts.

There were three cases recorded by Jenner³ in 1798 in which infants had been inoculated with cowpox. They were 6, 11 and 18 months of age and vaccinated with humanized lymph; i. e., arm to arm transfer of

virus. Two were successful, but Robert F. Jenner, aged 11 months, "did not receive the infection," although three older children inoculated with the same lymph, taken from the arm of William Pead, aged 8 years, had successful vaccinations.

Lack of appreciation and proper evaluation of Jenner's discovery in England in no wise deterred other countries from prompt adoption of this boon to mankind. Frobelius⁴ reported that the empress of Russia in 1801, after correspondence with Jenner, obtained from him humanized cowpox lymph, which under her patronage was employed at once in the foundling hospitals of Moscow and of St. Petersburg, in the latter it was used continuously in arm to arm inoculation until 1867, a period of sixty-six years, when it was supplanted by animal lymph obtained first from cows. In the St. Petersburg Foundling Hospital in 1801 and for many years thereafter, babies from 7 to 8 days old were regularly vaccinated with the Jenner lymph in six cuts in each arm. By 1817, 34,677 children had been vaccinated there without a fatality. The chief physician reported that the only observation worth mentioning was that there were children who were very slightly susceptible to vaccination and that it was necessary to inoculate some of them as often as twelve times to be successful.

Compulsory registration at the hospital afforded unique opportunity for observation of the foundlings up to 25 years of age. In the forty years 1826-1866 there were seventeen smallpox epidemics in St. Petersburg. Among an average of 15,000 living foundlings, all of whom had been vaccinated as required by decree of the czar before leaving the hospital, there were only thirty-six of them to have smallpox, and only one fatality, an infant aged 1 year. In 1867, 1,043 former inmates of the hospital were revaccinated, 13 per cent with good result and 9.9 per cent with irregular takes, and 88.6 per cent were reported as without result.⁵

The contention that arm to arm inoculation caused degeneration of vaccinal virus does not seem to have been borne out in the St. Petersburg Foundling Hospital. In 1867 the unsuccessful vaccinations there among 4,000 infants and children of the neighborhood were less than 1 per cent (0.8 per cent). Transfer of human disease was a disadvantage, erysipelas occurring in from 1.5 to 3.5 per cent among the inoculated, as well as a certain number of cases of syphilis. Vaccination alone was not responsible for erysipelas, for it occurred in some babies before inoculation and in others after recovery from vaccination.

These historical memoranda of Fröbelius⁴ are so closely related to our subject that they have been summarized.

Studies conducted to ascertain the possibility of intra-uterine vaccination have been almost uniform in revealing the consistent resistance of new-born infants to successful vaccination. The percentage of takes in new-born infants is revealed variously between 32.2 per cent and 100 per cent, averaging perhaps from 60 to 70 per cent.¹⁶

SOME OF THE OTHER LITERATURE ON VACCINATION

Bohn's² *Handbuch der Vakzination* is a classic presentation of the subject up to 1875, giving in addition a history of smallpox and vaccination prior to its publication. One of his conclusions is applicable at the present day: "We know a variety of things about vaccination, but not much, and a considerable part of these things quite inexact." ("Wir wissen Vielerei von der Vaccination, aber nicht viel, und darunter Vieles recht ungenau," page 355.)

In 1907 Pirquet's¹⁸ clinical studies on vaccination appeared and advanced the knowledge of this readily induced, artificial, virus disease. He lamented the fact

that the strength of smallpox protection is closely related to that of skin protection to revaccination; complete immunity or insusceptibility to revaccination is a temporary state.

What tissues or organs²⁰ are concerned in antibody production and protection cannot be positively stated, but protection against variola and revaccination specifically concerns the skin, probably the reticulo-endothelial tissues and possibly others. Vaccinations by other methods than the cutaneous do not take advantage of skin cell susceptibility and probable capacity for antibody production.

Jelinek²¹ revaccinated nineteen infants from one to three months after successful vaccination, five of whom reacted with frank pustule formation, areola and glandular swelling.

In the city of Paris in 1930, 78 per cent of 42,137 living new-born infants were vaccinated in the obstetric departments of Parisian hospitals.²² Successful inoculations amounted to about 67 per cent.

LIMITATIONS OF OUR STUDY

Our study of vaccination in new-born infants was undertaken in 1932 in the nurseries of the Gallinger

TABLE 1.—Some Previously Reported Vaccinations of New-Born Infants

Year of Publication	Author	No. of New-Born Infants	Ages	Virus Used	Technic of Vaccination	Percentage of 1st Vaccinations Successful	Comment
1879	Gast...	16	2 to 3 days	Human lymph diluted	6 to 12 skin cuts, both arms	100	Severe technic, virulent virus, small group
1882	Behm....	33	1 to 7 days	Human lymph undiluted	12 skin cuts, 6 in each arm	76	
1889	Ablass	120	Birth to 3 days	Human and animal, undiluted lymph	3 to 10 skin cuts and scratch	47	Successful; animal lymph 20%; human lymph 80%; severe technic
1889	Wolff	57	8 hrs. to 6 days	42 human, 15 animal lymph	5 to 8 skin cuts 0.5 cm. long	100	Severe skin trauma and thorough rubbing
1901	Palm..	43	1 to 3 days	Calf lymph (diluted?)	4 skin cuts	86	
1915	Franz and Kühner.	200	1 to 3 days	Calf lymph diluted	2 to 4 skin cuts; Borer	70	
1921	Mensching	684	1 to 3 days	Calf lymph diluted	4 skin cuts, each 0.5 cm.	72	
1932	Schlossmann and Herzberg-Kremmer	36	Days to weeks	Calf lymph diluted	2 skin cuts, each 0.7 cm.	58	Very slight skin trauma, intentionally
1933	Jelinek .	22	9 days to 9 wks.	Calf lymph diluted	Several skin cuts	77	Somewhat older infants
1934	Isaac	808	1 hour or less	Calf lymph diluted	Multiple acupuncture	32.2	Slight skin trauma

that much which had been known by the older vaccinators had been lost to the present generation and was not even to be found in modern textbooks.

When one attempts to formulate proper concepts of the duration of immunity to vaccination and to smallpox,¹⁹ in the light of what has been said, one almost is forced to abandon the attempt. It may be possible to state cautiously and undogmatically certain facts which relate to the subject:

Skin reaction to revaccination indicates the individual's degree of protection; in the early months following first vaccination he may be completely insusceptible; he may show varying alterations in skin reactivity, particularly after the first revaccination, the early appearance of these, the rapidity of the cycle, and the intensity of the reaction being indications of his state of immu-

nity. The strength of smallpox protection is closely related to that of skin protection to revaccination; complete immunity or insusceptibility to revaccination is a temporary state.

What tissues or organs²⁰ are concerned in antibody production and protection cannot be positively stated, but protection against variola and revaccination specifically concerns the skin, probably the reticulo-endothelial tissues and possibly others. Vaccinations by other methods than the cutaneous do not take advantage of skin cell susceptibility and probable capacity for antibody production.

Jelinek²¹ revaccinated nineteen infants from one to three months after successful vaccination, five of whom reacted with frank pustule formation, areola and glandular swelling.

In the city of Paris in 1930, 78 per cent of 42,137 living new-born infants were vaccinated in the obstetric departments of Parisian hospitals.²² Successful inoculations amounted to about 67 per cent.

LIMITATIONS OF OUR STUDY

Our study of vaccination in new-born infants was undertaken in 1932 in the nurseries of the Gallinger

Municipal Hospital and was hampered by the many limitations of an active maternity service, which made it necessary for us to cease observation of the babies as soon as the mothers were able to go home, on the average when the baby was from 9 to 10 days old. The majority were Negro babies, whose mothers shifted their dwelling places frequently, so that it was generally impossible to follow them in their homes. Seventy-three of these babies were revaccinated in the outpatient department of the Children's Hospital on almost the same day but were not seen again for a week or more, so that the terms immune and nonimmune used in the tables may not be exact, as sufficient opportunity for observation had not been available to employ these terms accurately. But it is to be borne in mind that these were first revaccinations, which if successful are usually not greatly different from first vaccinations. None the less, there may have been early or accelerated reactions that were not observed and therefore not recorded.

VIRUS EMPLOYED

The vaccine virus used was such as may be obtained from commercial biologic laboratories, diluted calf lymph.²³ Special pains were taken to keep it cold. The boxes of capillary tubes were placed in vacuum bottles to which was added a bit of dry ice, well packed, shipped by parcel post special delivery and received by us the following morning. The vacuum bottles were refrigerated at once at a temperature between 4 and 5 C. A day's supply was taken from this temperature in a well wrapped vacuum bottle to the nursery and promptly used.

METHODS OF VACCINATING

The site selected for inoculation of the new-born infant was just below the head of the fibula on the left leg. With the first thirty-eight babies we practiced ten pressures through a drop of virus with the needle held tangentially to the skin surface²⁴ so that the point broke through the horny layer while the skin was drawn tense, without rubbing. Only twelve results (31.6 per cent) were successful (table 2). Twenty pressures of the needle with slight rubbing was successful in twenty-seven babies (22.2 per cent) and doubtful in four. Thirty-nine received thirty pressures and moderate rubbing of the site with the flat of the needle; in fourteen (36 per cent) this was successful and in eight doubtful. Fifty-seven babies received thirty pressures and marked rubbing of the lymph into the site; in forty-three (75.4 per cent) it was successful and in one doubtful. Fifty babies received thirty pressures and moderate to severe trauma by rubbing with the needle; in thirty (60 per cent) it was successful. It was now clear that the percentage of successful vaccinations with the virus lymph that we were using was increased by rubbing the lymph into the traumatized epidermis. Severe traumatization by thirty strong needle pressures and rubbing of the lymph into the skin with the flat

* More takes result when the virus is rubbed into traumatized skin. New born babies are very resistant to successful vaccination.

of the needle backward and forward, and in the same way in a direction at right angles to the first, were therefore carried out in the next 289 consecutive vaccinations.

23. The virus employed in this study was supplied to us gratis by Dr. John F. Anderson, director of E. R. Squibb & Sons' Biological Laboratories. Serials 1 to 377 were vaccinated in 1932 with the same lot, 48784; vaccinating was begun again after an interval of ten months and other lot numbers were used but prepared in the same manner. Dr. Anderson states: "After the pulp is taken from the animal (calf) it is ground into a smooth emulsion and diluted with three parts of sterile 50 per cent glycerin solution. After this has been thoroughly mixed by further grinding, it is passed through a fine mesh wire sieve to remove the gross particles of tissues. . . . Each batch of vaccine, after this dilution, is tested on rabbits before being filled into the capillary tubes for distribution. The test made is that described some years ago from the National Institute of Health and is performed by vaccinating rabbits with vaccine diluted one part of vaccine in 1,000 parts of physiological salt solution and one part in 3,000 parts of physiological salt solution. It is required that both of these dilutions of the vaccine from every lot must show good takes or otherwise the vaccine is not considered satisfactory for distribution and is disposed of."

24. Leake, J. P.: Questions and Answers on Smallpox and Vaccination, Pub. Health Rep. 42: 221 (Jan. 28) 1927.

At the conclusion of the vaccination there was a slight serous ooze at the site of inoculation. Two hundred and sixty (90 per cent) of these babies had successful takes.

As has already been pointed out, successful vaccination of new-born infants depends on several factors. Potency of the virus is one of these. The lymph from

Fig. 1.—Vaccination on day of birth. Curves of skin reaction, weight and temperature.

a vaccination vesicle inoculated into the individual contains the most potent virus. Next to this humanized lymph in potency is undiluted calf lymph. Until recent years the European studies of vaccination in new-born infants were made with humanized lymph, then with undiluted animal lymph, and in the present century diluted calf lymph. When the stronger lymphs were used, successful vaccinations were obtainable with relatively little trauma, but as a matter of fact from two to twelve skin cuts were generally employed. When the lymph is less potent, in order to get generally successful results in new-born infants, the technic of vaccination must include severe traumatization of the skin. This we learned by experience. Primary vaccination is without value unless a take occurs. We therefore worked to secure takes and found that more takes resulted by increasing the skin trauma. It has been pointed out by Pirquet²⁵ and later by Schlossmann and Herzberg-Kremmer²⁶ that severe trauma is not desirable from other points of view. When one wishes to ascertain the effect of antiviral antibodies in the baby which have been received from the mother, or when one wishes to observe the altered reactivity or degree of immunity from a former vaccination, it is easy to see that a potent virus vigorously applied to the skin will break through these slight barriers and result in successful vaccination. Our problem was to develop a method that would successfully vaccinate new-born infants, and we worked toward that end. The vigorous technic developed had some disadvantage. Marked differences in new-born susceptibility were found, as had

been found since Jenner's time, and has been described. Pustules 20 mm. or more in diameter developed in 10 per cent of our takes. Not all these resulted from vigorous technic, but the majority of them occurred in this way.

THE SKIN REACTION

The papilla usually made its appearance on the fourth day, next most frequently on the fifth day, the day of inoculation being counted as the first day, next the third

TABLE 3—*Skin Reaction*

day, with diminishing numbers on the sixth and seventh days, rarely later (table 3). The maximum size of the pustules was attained on the seventh day most often, next on the eighth, ninth and sixth days; the fifth and tenth days had about the same numbers, with very few on the eleventh and fourth days. The limitation of opportunity for observation, because of the babies being taken home, interfered with the complete records in this regard. Some of the pustules undoubtedly increased in size after the babies left the hospital. Furthermore, their stay was too short for us to observe areola forma-

ciable depth and no appreciable involvement of the papillary layer of the skin or deeper.

CONSTITUTIONAL REACTION

Fever was almost entirely absent. When present it was insignificant and transitory, and we could never attribute it with certainty to vaccinia.

The vaccinated new-born infants behaved in practically the same way as the other babies in the nursery who were not vaccinated. Their appetites were good, their bowel functions normal, and their gain in weight quite comparable to unvaccinated controls.

Suppurative²⁵ parotitis which bore no relation to vaccination occurred in one of the 500 babies.²⁶ There were no other fatalities in the group and no significant accidents or complications.

REVACCINATIONS

In order to ascertain whether immunity developed promptly, six babies who were successfully vaccinated at the ages of from 7 hours to 9 days were revaccinated when from 4 to 7 weeks old (table 4). The technic employed was the most severe in this group and in the group of revaccinations to follow, of any that we used; the virus, the vaccinator and the time were all the same. Examination of the babies a week later showed no lesion whatever in four and moderately large pustules in two; nine controls of the same age who had never been successfully vaccinated all had well developed pustules at the end of a week. From this we conclude that four (66⅔ per cent) of the six babies had active, acquired immunity at from 4 to 6 weeks of age. As mentioned, hourly observation might have shown an early or accelerated reaction, but we think this most unlikely as it was their first revaccination and Pirquet states that complete insusceptibility is often present in the early months after the first vaccination. Ablass²⁷ revaccinated an

TABLE 4—*Active, Acquired Immunity Established in the Early Weeks of Life in 67 Per Cent*

No of Infant	No of New Born Infants	First Vaccination		First Revaccination		Second Revaccination		Indication of Immunity
		Ages	Result	Ages	Result	Ages	Result	
378	1	8 hours	0	9 days	Scar 5 × 5 mm	7 weeks	Pustule 15 × 15 mm.	Nonimmune
408	1	13 hours	0	8 days	Scar 12 × 12 mm	1 month	0	Immune
429	1	16 hours	0	8 days	Scar 8 × 7 mm	5 weeks	0	Immune -

							14 × 8 mm., 10 × 10 mm	
485	1	50 hours	0	6 days	Scar 7 × 7 mm	4 weeks	0	Immune
438	1	7 hours	Papule 8 × 6 mm, no induration	6 weeks	0	Immune
Totals	6		5 unsuccessful, 1 successful		5 successful, 1 unsuccessful			2 33% nonimmune 4 67% immune
398, 399, 411, 413, 433, 435, 455, 464, 468	9	1¾ hours to 28 hours	0	6 days to 9 days	0	1 to 2 months	Pustules 15 × 12 mm. to 20 × 20 mm.	These are controls: same virus, same method, same time; all had takes

tion in many of the babies, and we feel that discussion of this important phase of the skin reaction must necessarily be omitted. Measurements of maximum size of the pustules, while inaccurate, are perhaps not far from the truth; 61 per cent were under 9 mm. in diameter; 29 per cent were between 10 and 19 mm. in diameter; 27.3 per cent were only 4 mm. or less in diameter, and 10.1 per cent were 20 mm. or more across

THE CICATRICES

Examination at from 13 to 16 months of age of fifty-two babies successfully vaccinated at birth showed in each instance a soft, superficial scar with scarcely appre-

infant thirty-eight days after successful vaccination at birth and fourteen days after complete healing. He used undiluted humanized lymph, but the result was negative. Furthermore, this is what one would expect from Welch's observations already noted: Two babies born in the Philadelphia smallpox hospital of mothers suffering with varioloid were vaccinated successfully at birth; one spent three weeks and the other four weeks in the smallpox hospital with their mothers and failed to develop this disease.

²⁵ Elterich, T. O. Purulent Parotitis in the New Born, *J. Pediat* 3:761 (Nov.) 1933
²⁷ Ablass, Rudolf. Die Impfung Neugeborener, Inaug. Diss., Greifswald, 1889

Fifty-two babies successfully vaccinated at birth were revaccinated first at from 13 to 16 months of age by our severest technic (table 5). At the end of a week thirty-six showed nothing whatever in some cases and a few small papules in others, while sixteen showed well developed pustules: in fourteen between 10 and 20 mm. in diameter, in one 8 by 7 mm., and in one 30 by

TABLE 5.—*Immunity to Vaccinia Found in 69.2 per Cent of Babies 13 to 16 Months Old, Who Had Been Successfully Vaccinated at an Average Age of 24 Hours*

Age When First Vaccinated	Result of Primary Vaccination	Age When Revaccinated	Result of Revaccination	Immunity
Minimum, 3½ hours; maximum, 125 hours	All had successful "takes"	Minimum, 13 months; maximum, 16 months	Successful, 16; unsucessful, 36	Nonimmune, 30.8%; immune, 69.2%
Average age, 24 hours	Successful	Average age, 14½ months	Total number, 52	Immune, 69.2%

TABLE 6.—*Questionnaires Returned by Mothers of Vaccinated New-Born Infants*

Questions	Yes	No	No Answer	Total	Yes, per Cent
1. Is your baby vaccinated by us at birth getting on well?	138	8	..	166	95
2. Did the vaccination get along all right?	156	9	1	166	94
3. Would you want us to vaccinate another baby in the same way?	138	20	8	166	83
4. What kind of a scar was left?	Small	Moderate	Large	None	No Answer

25 mm. From this we conclude that on their first revaccination when between 13 and 16 months of age, thirty-six (69.2 per cent) of fifty-two babies showed complete or almost complete immunity and sixteen (30.8 per cent) were nonimmune or at least had insufficient protection.

ATTITUDE OF THE MOTHERS

One hundred and sixty-six of the mothers answered and returned questionnaires relating to their babies who had been vaccinated by us at birth (table 6); 95 per cent stated that their babies were well; 5 per cent of them had died of other causes; 94 per cent stated that the vaccination had gotten along well; 138 (83 per cent) stated that they would want us to vaccinate another baby in the same way if one should arrive, whereas twenty (12 per cent) said no and eight (4.8 per cent) made no answer. Eighty-eight mothers regarded the resulting scar as small, fifty-seven as large, and three as moderate in size.

COMMENT

In 289 consecutive vaccinations of new-born infants with the best adaptation of technic of inoculation to our virus that we could develop, 10 per cent of the infants were resistant to success of their first vaccinations. There is certainly a resistance in new-born infants beyond that of older infants and children. Vaccinators from Jenner's time to the present have almost consistently found this to be true.

Passive immunity, as demonstrated by the presence of humoral antibodies for the first two or three months of life in a certain number of infants, all too inadequately explains this resistance.

In line with the idea that young, growing tissue may account in part at least for resistance to vaccination manifested by new-born infants is what one finds on analysis of Mensching's¹² results in the vaccination of 684 new-born infants. Eighty-two of them were premature. Of the successful inoculations, 72 per cent were full term babies, in contrast to 63 per cent of successful results in premature infants. In other words, premature infants offered considerably greater resistance to vaccination than babies born at term; their tissues were younger and growth was more active.

There appear to be notable differences in potency of vaccinia virus, and there are no definite standards by which potency may be judged. The standard enforced by the National Institute of Health²³ is doubtless adequate for practical purposes, but it scarcely measures potency so that lymphs in different parts of the world may be compared. Hence it is difficult to make comparisons of successful vaccinations reported by different workers. The size of the skin reaction and rapidity of its appearance depend on the quantities and strains of inoculated virus. Pirquet¹⁸ has shown also that dilution of virus lymph retards the skin reaction by a day or two.

The technic of inoculation is closely related to the quantity of virus introduced. But there is another fac-

Fig. 7.—Size of pustule: 10.1 per cent of the takes

tor in technic besides the quantity of virus introduced. This is the factor of skin trauma, the real damage to cells susceptible to reception and the multiplication within them of vaccinia virus. The most successful method employed by us injured epidermal cells into which the virus was rubbed in addition. The papillary layer and the upper subcutaneous tissues must have been traumatized by the severe rubbing with the flat of the needle after pressures with its point which broke through the horny layer and cut into the epidermis. A serous ooze was present at the end of the procedure.

Well refrigerated virus the relative potency of which has been learned by experience with it, and adoption of a suitable technic of vaccination for the particular virus in use, will give a proportion of takes amounting to 90 per cent or more, even in resistant new-born infants. Repetition of vaccination of first failures generally results in takes, although repeated revaccination may be necessary. Both physician and patient abandon

observers have stated the same thing, while Franz and Kuhner,¹² among a few others, state that the skin changes are essentially similar to those of older children.

SUMMARY

1. Smallpox vaccination of new-born infants is a safe procedure with negligible complications, with insignificant influence on growth and nutrition, and almost always without fever.
2. The skin reaction tends to be smaller and slighter in extent and leaves behind small, superficial scars when Leake's method is used.
3. Adjustment between potency of virus and inoculation technic may insure at least 90 per cent of successful results on first vaccination.
4. Since Jenner's time, vaccination of new-born infants has been practiced successfully.
5. New-born infants are highly resistant to successful results, possibly because of the resistance of growing, young tissues; but other factors mentioned may have an effect, as well as still others at present unknown.
6. Our study shows that active, acquired immunity may develop promptly and may persist well over a year, probably longer.
7. Observations on foundlings in St. Petersburg (Russia), vaccinated shortly after birth and continued until they were 25 years of age revealed among many

Fig 8—Size of pustule 27.3 per cent of the takes

too readily the effort. Variability in individual susceptibility is difficult or impossible to gage

What change if any may result in our technic and what results from the use of purer virus grown on tissue mediums remain to be seen.

In reporting our results, we stated that sufficient time for observation of the complete course of vaccination had not been possible because of the babies leaving the hospital, and for this reason facts with regard to full areola development could not be given. We had an opportunity in exceptional cases (fig. 1) to observe the skin reaction well into involution and even healing. From these observations we have a strong impression, but no more than an impression, that the areola formation, even at its peak, is relatively slight, by comparison with that of older children (figs. 2 and 3). The figures given for the size of pustules convey a similar impression (figs. 7, 8 and 9). Gast¹⁵ reported in 1879 the same thing in vaccinations of sixteen new-born infants. His protocols, however, in each case showed observation of the skin reaction after an interval of a week following inoculation. This was insufficient for exact observation on this point. Ablass,²⁷ on the other hand observed his cases generally through completion of the local process or longer and states with emphasis that in new-born infants it is extremely moderate by comparison with older children, and particularly that the areola in new-born infants was relatively slight. Other

Fig 9—Size of pustule 33.4 per cent of the takes

thousands of individuals a very slight morbidity in the presence of seventeen epidemics of smallpox during the forty years 1826-1866.

8. Vaccination at birth is a practicable means of increasing protection against smallpox in a large group of society in which it is most needed, who are prone to do without this protection for themselves and the community until forced to obtain it at school age.

9. For those who will procure vaccination between 3 and 6 months of age, when it is more easily performed with success, it need not be done at birth.

1612 Eye Street, N.W.

ABSTRACT OF DISCUSSION

DR. J. A. DOULL, Cleveland: The authors have made the interesting observation that the relative resistance of new-born infants to vaccinia, which has long been recognized, can be broken down merely by increasing the amount of trauma. With safety and the apparent effectiveness of this procedure established, the question naturally arises as to its importance in public health. At present the most common practice in the United States is vaccination at the time of school entrance. Vaccination at this age carries with it certain more or less remote hazards, which can be to a great extent obviated if vaccination is carried out in infancy. Vaccination as early as the first day, however, or even in the first week of life has another angle, which may cause a good deal of embarrassment not only to the physician performing it but to the public health profession. The first day and the first week are the time of greatest mortality from other causes, and death may be attributed, erroneously, to vaccination. This should be recognized by the physician when he applies smallpox vaccination as early as that period. A good deal of public health effort has gone into the achievement of immunization against diphtheria and against smallpox at 6 months of age. I agree with the authors that this is the policy which should be emphasized not only by public health authorities but by pediatricians. There is, however, I believe, a field for the authors' technic and it is this: In the presence of a smallpox epidemic it is well for physicians to recognize the fact that successful vaccination may be carried out in the new-born. As was emphasized, there is a group of people, perhaps the colored population of the South may be mentioned, which is exceedingly difficult to follow during the first year of life, and it may be that in this group the method will have a practical application.

DR. FRANK P. GENGENBACH, Denver: Last fall there occurred a small outbreak of smallpox in the Colorado General Hospital in Denver, starting with a case that had come in for another purpose. As a result, the rule went forth that every child and every patient in that institution must be vaccinated, and this included new-born infants. This vaccination was continued from Oct. 19, 1933, to May 10, 1934, when it was felt that the outbreak had been successfully controlled. Practically all the new-born were vaccinated on the second day. The total number vaccinated was 184. One premature infant required revaccination. There were about twenty-five infants that required revaccination, apparently because a particular supply of virus had lost its potency. However, these were all revaccinated, and all the infants left with good scars and without complications. In the meantime, through the efforts of the Visiting Nurses' Association and the prenatal clinics in Denver, the mothers were gradually educated to the idea of having their new-born babies vaccinated at the Denver General Hospital, which is the county hospital, the Colorado General being the state hospital. As the mothers found that no bad effects followed, they were quite willing to give this permission. As a result, they now have practically 100 per cent cooperation. From May 1, 1933, to Dec. 31, 1933, 452 new-born babies were vaccinated, all successfully, and from Jan. 1, 1934, to May 31, 1934, there were 307 new-born babies vaccinated, a total of 759.

DR. J. P. LEAKE, Washington, D. C.: I feel that the best service can be done to the new-born infant and its mother by vaccinating very early in life. The difficulty later, after it has passed out of the hands of the medical profession for anything except exceptional circumstances, is too great to let that opportunity slip. I should like to emphasize, too, what the authors said regarding the necessity of going into the literature and observing carefully primary vaccinations, preferably on the tenth and fifteenth days after vaccination, and secondary revaccination on the second or possibly the eighth day as the minimum. This observation and this vaccination, if research is to be made on the subject, cannot be left to the interns who are not thoroughly familiar with vaccination from

day to day and hour to hour in all its phases, and with the various literature. All are doubtless aware of the danger from tetanus, particularly in the use of vaccine shields. I might also add that any one who applies a dressing primarily at time of vaccination, attached to the skin, has just as little defense in case tetanus supervenes as one who does not use tetanus antitoxin in case of a trivial wound.

DR. H. H. DONNALLY, Washington, D. C.: I understood Dr. Gengenbach to say that he had had 100 per cent of successes, excepting a group of twenty-five babies vaccinated with a batch of bad virus and one premature infant whose first vaccination was unsuccessful. That is remarkable for so large a number. Ablass, Behm, Palm, Franz and Kuhner, Mensching, Schlossmann and Hertzberg-Kremmer, and a few others found in the literature, as well as ourselves, had difficulty in getting takes in new-born infants even though some of these authors used arm-to-arm inoculation, the humanized virus, which is the most virulent and produces the greatest number of successes. Next in virulence is the undiluted calf lymph, and finally diluted calf lymph. It would have been interesting in connection with this report of successes, if Dr. Gengenbach had told the technic and virus used, and who did the work, as well as whether the takes resulted from one inoculation or whether repeated inoculations were necessary. If a series of inoculations are given, it is possible to achieve success even though one vaccinates an infant as often as twelve times, which has been done. I think that this fact might emphasize the point that one should not give up when failing with one, two or three attempts, but keep on, and finally a successful inoculation may be obtained, which alone gives protection.

SPECIFIC DIAGNOSIS AND TREATMENT OF ALLERGIC DISEASES OF THE SKIN

PRESENT STATUS

ARTHUR F. COCA, M.D.

PEARL RIVER, N. Y.

If one should inquire which of the existing medical specialties would profit especially through a deeper knowledge of allergic disease, one would necessarily think first of dermatology. Some may suspect an ironical sense in this statement because of the fact that the sharpest criticism of the common diagnostic procedure used by allergists has come from dermatologists. However, the statement is not so intended, and it is really based on the fact that every recognized category of allergic disease affects the skin.

Thus, among the diseases of the skin the familial allergy (hay fever-asthma group) is represented by atopic eczema. This is sometimes proved to be due to allergens of the same type as those causing the other atopic diseases; the second category is epidermal allergy or contact dermatitis, a form of allergic sensitivity that is not familial and affects only the skin; the third form is the cutaneous manifestation of infectious allergy (type of tuberculin sensitiveness). Besides these there are the unclassified serum sickness and the similar condition caused by drugs; also the skin manifestations of "physical allergy."

The formulation of the problems of allergy, as well as the practical diagnosis and treatment of allergic diseases, requires the tentative classification of these conditions, and Dr. Sulzberger and I have attempted to present in tabular form the corresponding classification of three allergic conditions of the skin. This classification has been prepared from a practical point of view

rather than a scientific one and it is incomplete, because it does not include the pathologic differences, which are illustrated in the exhibit of Dr. Sulzberger and Dr. Wise.

It is impossible in this short space to discuss the table in detail and I shall emphasize only the following points of comparison between the first two categories: 1. In atopic eczema the excitants are antigens, i. e., produce antibodies (reagins), whereas in contact dermatitis they are nonantigens; i. e., no antibodies can be demonstrated. 2. The skin test in the inherited atopic eczema is made with aqueous extracts with the scratch method or by intracutaneous injection, whereas that in contact dermatitis is best made with an original raw material by surface contact (the patch test). This original material, if it is a fluid, may have to be diluted. It is not necessary to use an extract of the solid materials. One has no choice in the selection of the technic of skin testing in these two categories, because the patch test with aqueous extracts regularly results negatively in the familial allergies while the intracutaneous and scratch tests are often negative with the extracts in contact dermatitis. 3. Finally, in the case of the vegetable oils, the treatment of contact dermatitis by desensitization,

From the foregoing brief discussion alone, it is plain that, in order intelligently to test and treat one of these two conditions, the physician must first determine, if possible, to which group his patient belongs. This he may attempt to do by consideration of the distribution and character of the lesions, especially of typical early lesions, by the history of the case, and by inquiry as to the family history of inherited allergy. This decision is sometimes difficult or even impossible and in such a case the physician must make the tests with the suspected materials both with the aqueous extracts in the abraded skin and with the raw materials in the patch test.

It must be admitted that the specific diagnosis and treatment of atopic eczema has been in many cases disappointing. Indeed, one has the impression from pediatricians experienced in allergy, that this is rather an understatement of the facts. The general opinion seems to be that even the transferable positive skin reactions do not give reliable information regarding the excitant of the condition.

However, this experience is not different from that commonly encountered in the study of bronchial asthma and to some extent also in hay fever subjects.

*Classification of Three Common Types of Allergic Skin Diseases as Regards Specific Etiologic Diagnosis and Treatment**

	Nature of Excitants	Nature of Skin Test Material	Technic of Test	Reaction Time	Nature of Positive Reaction	Specific Treatment
Atopic dermatoses (familial occurrence)	Water soluble antigens, food proteins and inhaled substances	Aqueous extract or dried extract	Intracutaneous scratch, or indirect	5 to 10 minutes 20 to 30 minutes	Wheal and erythema, reaginic	Avoidance, if practicable; if not desensitization may be tried
Contact dermatitis (nonfamilial)	Thus far nonantigenic substances, often simple chemicals and vegetable oils	Original material, suspected substance or extracted vegetable oil	Surface contact or patch test	Usually several hours to several days	Erythematous or vesicular dermatitis, no antibodies	Avoidance, if practicable; in the case of vegetable oils, desensitization usually successful after 3-4 injections
Fungous dermatitis (eczematous dermatophytids)	Products of hyphomycetes and molds	Filtrate of broth culture	Intracutaneous or patch	Usually several hours to several days	Inflammatory papule and eczematous dermatitis, no antibodies	Desensitization is often successful but often tedious

* According to A. F. Coca and M. B. Sulzberger.

when avoidance is impossible, is usually successful; this stands in marked contrast to the experience, up to the present time, in the similar treatment of contact dermatitis due to excitants other than the vegetable oils. In atopic eczema due to a food, on the other hand, I am informed that the results of injections have been disappointing.

The differences I have just mentioned may be illustrated in the following two cases of sensitivity:

Patient A has suffered for years from a dermatitis affecting the cubital areas, the popliteal spaces and the skin behind the ears. The intracutaneous and scratch tests with aqueous extracts of wheat flour are positive; patch tests with the flour are negative, the dermatitis disappears when the patient stops eating foods containing wheat derivatives, and it recurs when wheat is returned to the diet. The result that follows attempts to desensitize this kind of case is usually unsatisfactory.

Patient B suffers from an eczematous eruption during the late summer. Patch tests with ragweed leaf or the extracted oil are positive and there is no wheal reaction to intracutaneous tests with ragweed protein. The proper treatment in this case is by the injection of a solution of the extracted oil of the plant. This treatment is successful in most instances.

The pessimistic expression of opinion as to the difficulties attending the specific diagnosis and treatment of atopic eczema are somewhat relieved by two recent progressive suggestions. Charles Mallory Williams has reported two instances of atopic dermatitis which cleared up after the surgical eradication of purulent infection of internal organs. These cases suggest that, like some cases of bronchial asthma, atopic eczema may sometimes be of infectious origin and not due to a sensitivity to a specific excitant mediated by reagins.

The second suggestion was made last year by M. B. Sulzberger.¹ It consists in the idea that atopic eczema may sometimes be due to specific sensitivity to inhaled substances. Dr. Sulzberger allows me to state that in a forthcoming paper he will describe just such a case, in which sensitiveness is shown to inhaled particles of silk though not to surface contact with silk.

The practical value of these two suggestions has yet to be tested in a group of suitable cases, and the treatment of the atopic category remains for the present in an unsatisfactory state.

On the other hand, the practical handling of a certain number of cases of the second category (contact dermatitis from plants) and of the allergic manifestations of

1. Sulzberger, M. B., in discussion on Walzer, Abraham, and Grobstein, Max: *J. Allergy* 4: 554 (Sept.) 1933.

fungous infections (the third category) has been distinctly improved through two different influences.

The diagnosis of contact dermatitis has been facilitated by the recent greater employment of Jadassohn's surface or patch test, and the proper manner of applying specific treatment of this condition has been indicated through the demonstration that the excitant of contact dermatitis in ragweed pollen is not the antigenic atopen that excites hay fever but an oily substance.² This oil has since been found to be as abundant in the ragweed leaf as it is in the pollen.

I have pursued this question with the cooperation of several clinicians in different parts of the country, some of whom will make individual reports of their cases. Most of these observers have obtained a high percentage of satisfactory results, which have been particularly impressive in those instances in which exposure was continuous during the treatment or after the lesions were healed. The weekly intramuscular injection of 0.5 cc. of a 1 per cent solution of the extracted oily substance dissolved in sterile almond oil has in a number of cases brought quick healing, and protection on subsequent natural exposure.

Some cases have been complicated by a multiplicity of excitants and in some instances the failure of treatment may have been due to the physician having overlooked an additional unsuspected excitant. If exposure is continuous, it is easy to determine how long the interval between the injections can be made without danger of recurrence of the lesions. This period in one case was about five weeks.

The second suggestion comes out of the finding by M. B. Sulzberger³ that the allergic excitant of *Monilia* (*Oidium*) is specifically different from that of the trichophyton group and has materially broadened the range of effectiveness of the desensitization treatment of some cases of obstinate fungous infection, for which there seems to be no other means of relief.

I have treated three patients according to Sulzberger's plan, all of which were much more sensitive by skin test to *oidiomycin* than to trichophytin. One of the three, a traveling salesman with large lesions on both forearms and elsewhere on the body, was unable to take the injections regularly and during the few months of his treatment his skin sensitivity remained stationary and his local condition remained unchanged. This case was later seen to be one of psoriasis.

Both of the other patients are completely free of their lesions, which had persisted in one for about two years and in the other for five years. Both had used various local treatments without benefit. In one, the condition began with an infection of the left thumb nail and spread to the skin of other fingers. After the injections with a mixture of trichophytin and *oidiomycin* were begun all local treatment was discontinued. After two months of weekly injections the condition was decidedly improved and two months later the treatment could be stopped entirely. There has been no recurrence in the succeeding five months.

In the third case the sensitivity increased markedly and the injection was followed quickly by an extension of the areas involved (both forearms and ears) with a decided reddening of the lesions and a lessening of the scaliness. The solution was diluted 1:100 and the interval before the next and also the following injection

was increased to nine and ten days respectively. By the fifth month the skin sensitivity had diminished so that the strength of the solution could be increased more than 300 times. The lesions were improving but the patient discontinued the treatment. Three months later all the lesions had disappeared and they have not recurred during the succeeding four months.

CONCLUSION

It may be fairly stated that the recent researches on the allergic diseases of the skin have materially extended the understanding of them and have definitely improved the specific methods of their diagnosis and treatment.

ACNEFORM ERUPTIONS OF THE FACE

ETIOLOGIC IMPORTANCE OF SPECIFIC FOODS

CLEVELAND WHITE, M.D.

CHICAGO

The etiologic importance of various articles in the diet in acne vulgaris has been a matter of dispute for a long time. The appearance of papular and papulopustular eruption on the usual areas of acne due to certain medicaments, especially iodide, is a well accepted clinical observation.

In a recent summary of the treatment of acne vulgaris, Wise and Sulzberger¹ state that, while clinical experience tends to show that a diet high in carbohydrates and sweets seems to make some acne cases worse, there is not an iota of scientific evidence that there is any disturbance of carbohydrate metabolism in acne. In many thousands of acne cases that have been examined by careful investigators, the average blood sugar and average sugar tolerance are in most instances normal. The latest substantiation of this opinion is the recent paper of Strickler and Adams.² They conclude that while a diet rich in sugar or the carbohydrates may be inimical for certain patients with acne vulgaris, laboratory examinations do not substantiate any actual changes in the blood sugar.

Urbach and Schmidt³ state that the cloak of darkness covering the principal question whether a patient with acne or with seborrhea is harmed more by excess of fat or carbohydrate has not yet been lifted. All in all, the evidence of the literature is that there is little real scientific foundation for the causation of ordinary acne vulgaris by the general classifications of foods.

A series of thirty-two cases has been studied in which there was a recurrent papular and papulopustular eruption of the body involving the usual areas in which acne vulgaris is ordinarily found. Some patients also had deep scars in these areas. These acneform eruptions have been found in these instances to be due to a specific food or foods; my opinion is still reserved as to the definite place of diet in ordinary acne vulgaris. This type of eruption varies from the ordinary acne in that there are no comedones and no seborrhea of the face or scalp, and in that it had not responded to the

usual acne therapy. The roentgen therapy may have caused these ordinary acne manifestations to have disappeared and the etiology of the residual eruption which persisted was determined to be either a single or a multiple food sensitization. A recent paper⁴ was published illustrating the preliminary studies of this type of eruption, in which one case was described in detail. Nine other cases of similar type are now being studied and as yet the rôle of a specific food or foods has not been ascertained; it is well recognized that other factors may at times be responsible.

In general aspects, these patients presented about the same history. Their ages ranged from 17 to 36; twenty were females and seven were married. The longest duration in any one patient was seventeen years. All the patients gave a history of receiving from twelve to thirty roentgen treatments with only temporary benefits. Four presented definite evidence of radiodermatitis on the face; i.e., localized areas of telangiectasia and atrophy were present on the cheeks. They had received the usual local treatment of lotions. Many had been placed on a low carbohydrate diet and others had had some general dietotherapy. A series of cases are now being studied which seem to fall in this group and have had no roentgen or ultraviolet treatment. It is still my experience that up to a certain limit roentgen therapy cannot be dispensed with in treatment of severe acne vulgaris.

All patients were in excellent general health. Endocrine studies, especially as to possible thyroid and ovarian disturbances in the female, were of little practical importance. Some did have a menstrual exaggeration, but this disappeared entirely in the series as the patient's eruption became less and less noticeable. Thyroid administration in cases in which it was indicated did not improve perceptibly the acneform eruption. The usual blood counts did not reveal any obvious anemia or blood alterations. The ordinary foci of infection, such as the teeth and tonsils, were investigated and did not show any clinical importance. Ordinary laboratory procedures showed no abnormal deviation.

The usual skin food tests were performed in a small number. As their importance in eliminating the causative foods was practically negligible, they were not continued because of the added expense and time to the patients. All patients were observed in private practice. The Prausnitz-Küstner method of passive transfer will be used at the first opportunity.

The sudden recurrences suggested that specific food or foods sensitization might be the etiologic agents. Rowe⁵ has stated that a patient who had had severe attacks of urticaria had been put on eliminating diets. Elimination diets relieved all her urticaria symptoms, including a severe, long standing acne on her face. He found that in this particular patient grapes and cantaloup caused her facial eruption to reappear. Unger⁶ has observed a somewhat similar case due to eggs. In general, few allergic symptoms have been present in this series. The precipitating cause of the sensitization to these foods and to localization in these areas is only conjecture at this time.

Wise and Sulzberger¹ are of the opinion that the ill effects of a relatively high intake of sweets and starches

may be due not so much to the actual high total carbohydrate intake but rather to an idiosyncrasy in reaction toward certain specific items in the carbohydrate diet. They particularly mention chocolate in any form and white bread. However, they stress that the etiologic agent in a person eating bread the eruption on the face may be due to so-called baking improvers that contain a high percentage of potassium bromate. The bromate in the baking process becomes reduced to bromide.

Theoretically, any food may cause such an acneform eruption; in this series the six most common were chocolate, milk, wheat, oranges, tomatoes and nuts. Some cases presented multiple food sensitization; in others, certain combinations produced new lesions. The causative food allergens were largely determined by using so-called elimination diets or "nonallergic" trial diets. As stated, the usual cutaneous food tests were of little or no value in the detection of the etiologic ingestant or ingestants.

The detective method of finding the causative foods was to place the patient on a nonallergic diet for one week, using as a basis the elimination or trial diets of Rowe.⁷ Only a minimum number of foods should be selected. In regard to a strictly balanced diet, I agree with Feinberg,⁸ who says he sees no need for a strictly balanced trial diet since the first diet is only used for a period of a week or two. Caloric requirements should be fulfilled, of course, especially in those who may be somewhat underweight, but slight deficiencies in minerals and vitamins for the periods involved need not cause concern. If a vitamin or mineral deficiency is feared, these materials can be added in concentrated form. If no lesions appear in a week's time, one can add a new food every two days, adding at first the least allergic ones. If the offending food was added, new lesions usually appeared in from two to six hours. Occasionally it took from twelve to twenty-four hours in some patients. This method had to be altered to fit the individual, and the diet has to be changed to meet the dietary demands of the patient, especially when a careful history showed that certain foods have not caused any new lesions as far as the patient has been able to detect. It simmered down to an individual study in each case. With a thorough knowledge of diet, one can use Rowe's elimination diets or those of Dale and Thornburg⁹ or those of Hopkins and Kesten.¹⁰ Rowe's diets with some variations were used in this series. That the constituents of certain foods have to be thoroughly known is strikingly illustrated in what is called rye bread. Lespinasse¹¹ has surveyed the rye bread in Chicago and finds that there is no such thing as rye bread. She found that rye bread in Chicago contains anywhere from 10 to 60 per cent of wheat. Other foods may be the cause of similar trouble.

Treatment of these cases consists naturally in the elimination of the causative foods when possible. There are four accepted methods of treating these food idiosyncrasies. These are well summarized by Urbach.³ The first has already been mentioned; that is, omitting the food. The second method consists in forbidding all animal and vegetable proteins for two weeks, as it is

stated that this method is beneficial only in cases of food idiosyncrasy of short duration. Naturally, this has been of no help in these cases. The third method is active desensitization by very gradually increasing the amount of allergen, by either the oral or the intracutaneous method. Oral administration with small doses of the offending food has been quite helpful in certain cases. Active desensitization by intradermal injections has not been used because of the technical difficulties and lack of assurance that it would produce a cure. The fourth method is based on the principle of skeptophylaxis, which usually induces complete desensitization if the method is carried out for three or four weeks. With the term skeptophylaxis Lambert, Ancel and Bouin¹² designated the following phenomenon: If an individual, from three quarters to one hour preceding the ingestion of fairly large amounts of an anaphylactic producing drug, food or peptone is given minimal amounts of the same drug, it is possible to prevent the occurrence of an anaphylactic reaction otherwise certain to occur. The mechanism of skeptophylaxis may be explained on the basis of what Besredka and Otto called antianaphylaxis. Nonspecific methods, as the use of the peptones in treating nutritive allergic dermatoses, have also been used.

This brings up the question of using specific peptone therapy, which was first brought into practical usage by Luithlen.¹³ He termed these partially broken down peptones propeptan. Neither the use of his and Urbach's¹⁴ specific food propeptans nor the use of ordinary peptone has been of any value in this type of food sensitization. Oral peptone therapy in my opinion has been of marked benefit in some eczematoid allergic dermatoses, as suggested by Miller.¹⁵

In patients who are not sensitive to certain fish livers or corn oil, viosterol can be used to raise the patient's threshold at times to certain foods. Yeast has been used by practically all; in several, it caused new lesions. The use of viosterol in acne was recently brought forward by Doktorsky and Platt.¹⁶ Along this line, ultraviolet irradiation is a definite aid in raising the resistance to certain foods in some cases. In several young women the viosterol caused such irregular menstruation that its further use was abandoned. Use of the vitamin D as viosterol and ultraviolet irradiation has prevented new lesions, which had occurred from previously taken smaller amounts of allergic foods in several patients.

CONCLUSIONS AND SUMMARY

Specific food or foods have been found to be the cause of an erythematopapular and papulopustular eruption of acneform distribution in some thirty-two cases. Scarring occurred in some cases.

The usual roentgen treatment for acne vulgaris had been given in other hands with only temporary results; unfortunately, four presented definite evidence of too much roentgen treatment.

The causative food allergens had been determined by the use of elimination or "nonallergic" trial diets, as the ordinary skin tests were of little or no value.

LIGHT SENSITIVE DERMATOSES

NELSON PAUL ANDERSON, M.D.

AND

SAMUEL AYRES JR., M.D.

LOS ANGELES

The problem of light sensitivity is one in which the final solution will probably be found by the biochemist. It appears to be bound inseparably with sulphur metabolism, and through sulphur metabolism with the amino acids and perhaps also the vitamins.

A review of some of the recent work on sulphur metabolism is certainly pertinent to the question of light sensitivity. Harris and Hoyt¹ subjected parameria to the effect of ultraviolet rays that had previously

passed through a solution of cystine $\left[\begin{array}{c} \text{NH}_2 \\ | \\ \text{CH}_2\text{S}-\text{CH} \\ | \\ \text{COOH} \end{array} \right]$,

in sodium hydroxide. They found that the time of exposure required to produce fatal results was 1,200 seconds if the ultraviolet rays first passed through the cystine solution, as compared with 150 seconds in the controls. From this they argued that the susceptibility of protoplasm to ultraviolet radiation was conditioned by the selective absorption of the toxic rays by cystine and certain aromatic amino acids. Confirmation of this effect was accomplished by the study of Ward² on the absorption spectrums of amino acids. He found that cystine was the only amino acid that had any marked absorption in the region of solar ultraviolet rays. In the following year Lewis³ made the suggestion that the relatively high concentration of cystine in wool and hair was of physiologic significance in the protection of the organism against the harmful effects of prolonged exposure to sunlight. Ward further called attention to the fact that the curious custom of the Arabs of wearing heavy woolen clothing may have a strong justification in the protective effect of the cystine in the wool.

The following remarks are taken from Smith's⁴ monograph, a review of the subject of sulphur metabolism and the relation of cystine to solar irradiation. About 1920 Sullivan and his co-workers⁵ suggested that there was an abnormal sulphur metabolism in pellagra. Others,⁶ however, as early as 1910 had reported such abnormalities.

It appears rather definitely that the demands of the organism for sulphur are supplied largely by that sulphur-containing amino acid cystine. This amino acid is necessary not only for the growth but for the maintenance of animals as well.⁷ The function of cystine in the organism appears to include not only an important bearing on the oxidation of tissue through the reversible cystine \rightleftharpoons cysteine reaction,⁸ but also a detoxifying influence on certain compounds, one of

which at least, cyanogen, is a product of protein metabolism.

The high content of sulphur and cystine in epithelial protective tissue, e. g., the horny layers of the skin, hair and nails, a content greater than that of any other tissue of pure protein, suggests that the cystine may have a specific function in this tissue. Lightbody and Lewis,⁹ Klauder¹⁰ and others have discussed the relation of the protein and sulphur content of the diet to the growth of hair in both animals and man. In general, however, Lewis, who has thoroughly studied the question, holds that experiments which indicate a special relation of cystine to the growth of epidermal tissues rich in sulphur (hair and wool) are interesting but that further work under carefully controlled conditions is necessary before the specific rôle of cystine in the growth of hair can be accepted without qualification.

Cohn¹¹ stated that most of the known proteins are poor in tryptophan and cystine; nevertheless their necessity for growth in the young and for maintenance of nitrogen equilibrium in the adult animal is fully attested. As Smith states, "in view of the poverty in cystine which characterizes proteins generally, it is of interest to note its occurrence in the foods that Goldberger and his associates advocated as preventive of pellagra and to note that these foods contain cystine (sulphur) in proportions comparable to the value for the prevention of the disease assigned them by this author."

HEMATOPORPHYRIN

The problem of light sensitivity cannot be discussed without some consideration of the porphyrins. The term "hematoporphyrin" is somewhat loosely applied to the iron free pigments that are obtained from hemoglobin, hemochromogen, hematin or hemin by the action of strong acids. As Pryde¹² points out, the presence of a porphyrin is one feature that is common to the hemoglobins, the chlorophylls and other similar substances.

Hematoporphyrin has long been known as possessing a very powerful light sensitizing action. When injected into either man¹³ or experimental animals, this porphyrin causes them to become extraordinarily sensitive to the deleterious effects of ultraviolet irradiation and in other ways increases the response of many tissues to stimuli by ultraviolet rays.

It would simplify the problem of light sensitivity a great deal if it could be shown that hematoporphyrin or one of the other porphyrins was the underlying cause of light sensitivity. When the evidence is looked at critically, however, one can only say that the rôle of the porphyrins in photosensitivity is still unsettled. In hydroa vacciniforme, for example, hematoporphyrin has been demonstrated in only about 25 per cent of the cases,¹⁴ and, further, there are many cases in which hematoporphyrin is present in the urine but in which no light sensitivity exists. In none of our own cases

of light sensitivity that were tested have we been able to detect hematoporphyrin. Templeton and Lunsford¹⁵ were able to produce porphyrinuria in eleven patients not sensitive to light, merely by ultraviolet irradiation, and found that porphyrinuria also occasionally occurred in patients showing a widespread dermal irritation from dermatoses not related to light. They came to the conclusion that porphyria was probably a result rather than a cause of dermal sensitization.

The whole question of the porphyrins and light sensitivity needs further research. The older observations regarding hematoporphyrinuria need to be reviewed and revised through the light of modern research on these complex chemicals. Thus it must be pointed out that hematoporphyrin as known to biochemists, that is in its strict sense, is never found in man. It is an artificial and synthetic product of the laboratory. Uroporphyrin, however, is present in large amounts in the urine of photosensitive patients and is considerably more active in producing photosensitivity than coproporphyrin, which is found in large quantities in the urine of patients with acute hematoporphyrinuria. Patients with acute or idiopathic hematoporphyrinuria and patients with toxic hematoporphyrinuria are rarely light sensitive.¹⁶

More reports are needed like those of Taussig,¹⁷ who demonstrated the presence of uroporphyrin in the port wine colored urine of one of his patients with hydroa estivale. In other words there is need in future for cases of light sensitivity, that the exact porphyrin present may be determined.

LUPUS ERYTHEMATOSUS

The irritative effect of sunlight on lupus erythematosus has long been known. In fact, sunlight not only aggravates this condition once it has appeared but in many instances seems to be the provoking or precipitating cause. In many of the reported cases, lupus erythematosus has followed a severe sunburn and in other cases the disease has been changed from that of a chronic discoid type into one with a widespread dissemination of the lesions.¹⁸

The question of a tuberculous background for this disease is still open for discussion. The only real progress, however, that has been made in recent years in the treatment of lupus erythematosus—namely, the use of gold compounds—was based on a tuberculous etiology. The observations of Gross and Volk¹⁹ indicated that following an injection of a filtrate of dead tubercle bacilli there was a decided sensitizing effect to sunlight. This may perhaps explain both the light sensitivity in lupus erythematosus and the untoward results obtained by treatment with tuberculin. In addition, Randak²⁰ has demonstrated in a case of disseminated lupus erythematosus that even the uninvolved portions of the skin were oversensitive to light.

It has been our impression that gold compounds, while a distinct advance in the treatment of this condition, are not a cure-all. We wish particularly to stress the importance of small doses of gold and sodium thiosulphate and feel that the therapeutic results

obtained with smaller dosage will equal or exceed those with larger doses of this drug with less likelihood of toxic reactions. Our initial dose never exceeds 5 mg. of gold and sodium thiosulphate, and we rarely exceed from 30 to 35 mg.

Just how or why bismuth acts in this disease we do not know, but in cases resistant to gold therapy a trial of bismuth therapy is certainly indicated. We use an insoluble preparation, bismuth subsalicylate in 2 grain (0.13 Gm.) doses once a week. Sutherland-Campbell, however, recently presented two cases of chronic resistant lupus erythematosus before the Los Angeles Dermatological Society. Both of these cases had been treated for several years by gold compounds without result. This was followed by a series of bismuth salicylate injections—some twelve to sixteen in number—and these, too, were without effect. Finally an excellent therapeutic result was obtained with the use of iodo-bismutol. Certainly its employment is indicated in cases resistant to other types of therapy.

In all cases of lupus erythematosus that we have seen, the removal of foci of infection has been stressed.

REPORT OF CASE

We have recently made an interesting observation concerning the effect of diet on lupus erythematosus:

A white woman, aged 35, had had a chronic type of disseminated lupus erythematosus for about thirteen years. She presented an extensive but typical involvement of the face, the V of the neck and chest, with some eruption on the extensor surfaces of the arms. She was first started on gold therapy in September 1932 and received a total of twenty gold injections. Toward the latter part of this course, signs of intolerance began to develop and the treatment was temporarily suspended, one injection of ordinary sodium thiosulphate being given. At this time, March 6, 1933, there was considerable involvement of the forehead and cheeks. She was not seen again until Jan. 27, 1934. At this time her face was entirely free from any lesions. On inquiry the patient stated that the eruption became progressively worse after she disappeared from our observation and was as bad as it had ever been. In June 1933 she started on the diet of a well known food faddist and stated that within one week after starting this diet her face was 95 per cent well and at the end of two weeks she was entirely well, there being no sign of any eruption on her face. The diet which she had used was as follows:

7 a. m., one teaspoonful of vegetable salt in a glass of hot water.

8 a. m., one glass of orange juice and at every hour till noon some kind of fruit.

12 noon, a salad of raw vegetables and two cooked vegetables. Every hour in the afternoon a piece of fruit or fruit juice. 6 p. m., a salad of raw vegetables and two cooked vegetables. Prunes or baked apple or fruit.

A vegetable broth, which the patient could drink at any time, was prepared as follows: 3 cups of ground carrots, 3 cups of ground celery, 1 cup of ground spinach and one-half cup of ground parsley. This was ground fresh and put into 2 quarts of luke warm water and placed on a slow flame for twenty-five minutes only. This was allowed to stand for one hour and then was drained through cheese-cloth. The bulk was thrown away. To this liquid tomato juice or juices from ground vegetables were added.

Since this observation we have tried this diet on about six patients either with lupus erythematosus or with an actinic dermatitis. Several of the patients have been helped, one to the extent of perhaps 75 to 80 per cent and another to an extent of at least 50 per cent, and this within a period of two weeks' time. Two patients, one with a severe actinic dermatitis, were unchanged.

Just what this diet does in these cases we are not prepared to state. There is apparently no rationale in its use.

But if we knew the exact cause of lupus erythematosus or actinic dermatitis it is possible that we could study and use those parts of this diet which would be beneficial. Before the use of such an apparently fantastic diet is condemned, one should remember such things as the ketogenic diet in epilepsy, liver diets in pernicious anemia, the Gerson-Herrmannsdorfer-Sauerbruch diet in tuberculosis of the skin, and the fact that dietary changes may be both the cause and used as the cure of pellagra, the skin changes of which certainly belong in the realm of light sensitive dermatoses. In experimental work on arspenamine sensitivity in rabbits, Sulzberger and Mayer²¹ have given reasons to believe that diet may play a leading rôle. Whatever may be the final status of diet in the treatment of lupus erythematosus, whether it acts through changes in mineral metabolism, through vitamins or by changing the intestinal flora, the fact remains that diet may play more of a rôle than can at present be admitted. Incidentally, Urbach²² in his recent work on skin diseases and nutrition mentions several cases of lupus erythematosus in which a marked improvement or cure took

Fig. 1.—Case of chronic, disseminated lupus erythematosus. Temporary improvement after 2 weeks on diet as in figure 2.

Fig. 2.—Same patient as in figure 1. Patient apparently cured after following a modified Gerson diet, consisting essentially of fruits and vegetables and total exclusion of salt, with a vegetable salt substitute.

21. Sulzberger, M. B., and Mayer, R. L.: Sensitization—Regional, Seasonal, Dietary and Other Influences Accounting for Variations and Fluctuations. *Arch. Dermat. & Syph.* 24: 537 (Oct.) 1931.

22. Urbach, L.: Skin Diseases and Nutrition. *Schmidt's English Translation, Vienna, Wilhelm Maudrich, 1932, pp. 182-183.*

place following the use of the Gerson-Herrmannsdorfer-Sauerbruch diet.

LIGHT SENSITIVITY DUE TO DRUGS

There are a number of drugs or chemicals which, if given internally, possess the property of sensitizing the skin to sunlight. Among these drugs are arsenic, phenobarbital, hematoporphyrin, eosin, acriflavine hydro-

Fig. 3.—Eruption on the face variously diagnosed as an atypical lupus erythematosus or an erythema annulare centrifugum treated for over a year with gold and bismuth without any result. Same patient as in figure 4.

chloride, methylene blue, rose bengal, erythrosin and chlorophyll zeochin (from corn). Most of these substances named possess the common property of fluorescence, which property seems to bear some connection with the ability to photosensitize.²³

Haxthausen²⁴ has reported an interesting case in which a psoriatic patient was given acriflavine hydrochloride intravenously for the purpose of making therapeutic use of this sensitizing effect. Previous to the treatment the patient had been very tolerant of sunlight, but following the injection of acriflavine hydrochloride and the use of ultraviolet rays her skin developed a marked intolerance to sunlight. This was so severe as to necessitate her remaining indoors almost constantly. However, even bright sunlight was without effect if the windows were closed. Haxthausen showed that the hypersensitivity of his patient to light was not limited to the exposed areas, for example, the face and hands; by filtration experiments he proved that the sensitivity of the patient was due to the shorter ultraviolet rays; e. g., those less than 4,000 angstroms.

One must not forget that light sensitivity may be produced by the external application to the skin of drugs or chemicals. The photosensitizing action of crude coal tar is well known, which, by the way, fluoresces beautifully under a Wood's filter. The cases of Berloeq dermatitis belong to the same category.

Whether it will be possible to use the property of light sensitization which certain drugs possess is problematic. Macht and Anderson²⁵ used eosin as such a sensitizer in the treatment of pernicious anemia. They felt that its action was such as to increase the detoxifying efficiency of the ultraviolet rays.

VITILIGO

Sunlight is certainly a factor in the production of many cases of vitiligo. The frequency of its occurrence after sunburn or other exposure to the elements and the greater involvement of exposed areas point to sunlight as an etiologic factor. The normal reaction of ultraviolet irradiation on sound skin is accompanied by the development of pigmentation or tan. The pigments so formed are certainly the melanins, and possibly they are melanins which contain sulphur, although natural melanin, which is formed from the amino acid tyrosine by the action of the enzyme tyrosinase in the presence of oxygen, does not contain sulphur. It is possible, how-

Fig. 4.—Same patient as in figure 3. Result of one month's dietary treatment on a salt free fruit and vegetable diet.

ever, as Pryde points out, that true sulphur-containing melanins of natural origin may exist. But nothing is known of their possible mode of formation. Lewis,³ however, states that the sulphur content of the various melanins is well known, and he cites Brahm,³⁰ who

23. Blum, H. F.: Photosensitization, *Ann. Int. Med.* 6: 877 (Jan.) 1933.

30. Brahm: *Arch. i. path. Anat.* 227: 137, 1920, cited by Lewis.³

found 3.42 per cent of sulphur in melanin from a tumor. Brahm suggested that the pigment might be a phenyl derivative of cysteine, (3,4-dihydroxyphenyl-cysteine).

One of our cases of actinic dermatitis occurred on the exposed areas of a Japanese man engaged in outdoor work. He had suffered from a vitiligo for some twenty years, and it had gradually involved a great deal of the body surface. Incidentally his hair had started

Fig. 5.—Same patient as in figure 6. Acute disseminated lupus erythematosus showing involvement of the exposed areas. Such an eruption often follows a severe sunburn in an apparently normal individual. However, exposure to sunlight may cause dissemination of the disease in a patient with chronic discoid lupus erythematosus.

to turn gray when he was 20 years old—certainly an uncommon occurrence in his race. About four years before he had taken up outside work and since then had been troubled with a continuous and severe eczematous process involving particularly the face and the backs of the hands. His improvement after four doses of a bismuth compounds was quite remarkable, and he also stated that he felt a great deal better physically.

What rôle arsenic may play in the production of vitiligo as advocated recently by Cannon and Karelitz³¹ and whether sodium thiosulphate acts in this disorder by favoring the elimination of arsenic or by furnishing sulphur to the body is a debatable question. We only know that in vitiligo a negative dopa reaction occurs, which means the absence of dopa-oxydase or the pigment-forming ferment. Whether arsenic interferes with the formation or action of this ferment is at present unknown. It is even possible, as Cannon suggests, that it may act by stimulating the process of pigment formation to a point of exhaustion.

ACTINIC CHEILITIS

It seems worthy of note that practically all cases of actinic cheilitis that we have observed have been in persons of the dark skinned races, notably Mexicans and Japanese. Treatment with gold and sodium thiosulphate and with bismuth compounds has been of no avail. We have not determined the presence of hemato-porphyrin in this group of light sensitive cases. It seems more probable that a local tissue hypersensitivity exists, as in one case the condition was markedly ameliorated by destruction of the mucous membranes by the electrodesiccating current. It is worth while to note that in at least three instances we have seen patients with an actinic cheilitis who returned several years later with prickle cell epitheliomas of the lip.

ACTINIC DERMATITIS AND HYDROA ESTIVALE

Little has been added to the knowledge of hydroa estivale since Senear and Fink's³² review of the subject over ten years ago. There has, however, been a considerable advance made in the chemistry of the porphyrins, which was mentioned earlier in the paper. We have seen a considerable number of cases that might be classed either as actinic dermatitis or hydroa estivale. We have attempted in these cases to demonstrate the presence of photodynamic substances in the urine and

Fig. 6.—Same patient as in figure 5. Apparent cure of acute disseminated lupus erythematosus following the removal of foci of infection (tonsils), protection from overexposure to sunlight, and desensitizing injections of autogenous vaccine. The vaccine was made of organisms grown from the removed foci (teeth and tonsils).

in so doing have utilized the method recently proposed by Perutz and Lustig.³³ For this purpose two strips of sensitive photographic paper, which are of the same

33. Perutz, A., and Lustig, B.: Simple Method for Demonstration of Photodynamic Substances in Urine, *Wien. klin. Wchnschr.* 46: 1579 (Dec. 29) 1933; abstr. *J. A. M. A.* 102: 733 (March 3) 1934.

size, are used. One strip is half immersed in the urine to be examined and the other into a normal control urine, which has the same color and specific gravity as the urine to be tested. After one minute both strips are removed and exposed to either actual sunlight or ultraviolet radiation. As soon as the nonimmersed portion of the paper has turned brown the light exposure is stopped and the colors of the papers are compared. They found that urine from photosensitive patients always produced a darker coloration. Our results unfortunately were not confirmatory of their observations, as we found the light reaction suggestive in only one case.

We have also attempted, in all cases in which light seemed to play a rôle, to demonstrate the presence of fluorescent substances in the urine of such individuals by means of examining the urine under a Wood's filter.

Fig. 7.—Lichen planus. An unusual example of an acute lichen planus precipitated by exposure to the sun. Areas covered by the bathing suit were free of eruption at first; lesions were present on the buccal mucosa.

This procedure was suggested by the work of Jausion and his collaborators,³⁴ who reported a case of solar eczema in a man, aged 51. They were not able to demonstrate hematoporphyrin in his urine but stated that the patient's urine was more fluorescent under a Wood's filter than the urine of three normal individuals. In such an examination of the urine from at least a dozen light-sensitive individuals we were not able to confirm this finding.

Jausion also has made an interesting suggestion regarding the use of auto-urine therapy in such cases. He injected intramuscularly a small amount of freshly passed urine to which had been added an antiseptic such as phenol or ether. This was done on the basis that the urine contained an antigenic substance which acted

to sensitize the patient to light, and the auto-urine injections were given to decrease or abolish this sensitivity. We have not been able as yet to try this procedure, although Jausion has reported excellent results in several cases.

Uhrbach³⁵ has suggested the use of a liver diet in cases of actinic dermatitis and cites several instances in which good results were obtained in such cases, the purpose of the diet being to protect liver function.

PELLAGRA

In the production of the skin lesions of pellagra, light certainly plays a very important rôle. This has been recognized almost as long as the disease itself and was beautifully shown by the experiments of Ormsby, who demonstrated conclusively that if patients in the early stage wore fenestrated gloves, the dermatitis appeared only in the areas of skin directly beneath the windows cut in the gloves. That light itself, however, is not the sole cause of these lesions is evident from the fact that involvement of unexposed areas, particularly the perineum and genitals, occurs. Smith, however, has explained involvement of these normally pigmented areas on a phylogenetic basis.

It is interesting in this connection to mention the disease of fagopyrism,³⁵ which occurs only in white or lightly pigmented sheep, hogs or cattle. Its cause has been shown to be a chemical compound, flurophile, which is present in the buckwheat eaten by these animals. The disease presents erythema, edema, vesiculation and at times necrosis. But this condition manifests itself only after such animals are brought out into the sunlight in the spring. In spotted animals the condition occurs only in the nonpigmented regions of the skin. Thus it is seen that two factors are necessary for its production: (1) exposure to sunlight (external) and (2) eating of buckwheat (internal).

Since sunlight must be a factor in the production of pellagra, the idea that disturbed sulphur metabolism also plays a rôle is probable. It is only necessary to recall what was mentioned before; namely, the protective action of cystine against ultraviolet radiation.

Hematoporphyrin is not present in the blood serum of pellagrous patients,³⁶ nor has any one ever shown the actual presence of a photosensitizing substance in pellagrous patients. Jobling and Arnold,³⁷ however, recorded experiments tending to show that pellagra might be the result of the absorption from the intestinal tract of photodynamic substances produced by certain fungi when the diet consists largely of carbohydrates. Modern biochemical research, however, apparently places the light sensitivity of pellagra as being due not to the presence of some photosensitizing chemical but to the absence or disturbed metabolism of some light protecting mechanism.

The fact that yeast is curative in pellagra may take on a new significance when it is recalled that Koch and Sugata³⁸ showed that cystine actually stimulated the growth of vitamin B containing yeast.

The common occurrence of either a hypo-acidity or an achlorhydria (from 80 to 90 per cent) with an absence of pepsin has long been noted in the pellagrous

patient. Their occurrence, however, assumes more importance when the biochemist explains that pepsin is required to produce the change in the protein molecule whereby a positive nitroprusside reaction occurs. This reaction occurs only in the presence of the SH or sulphhydryl group. All in all, as Smith says, "the evidence is suggestive that a lack of cystine may have a specific relation to the etiology of pellagra."

Recent clinical work, notably that of Sabry,³⁹ gives additional evidence of disturbed sulphur metabolism in pellagra. He found that injections of sodium thio-sulphate caused a checking of the skin lesions in early cases of pellagra and a prompt disappearance of the dermal lesions in the late or advanced cases. Other symptoms too were cleared up. Sabry felt that the symptoms of pellagra were due to a poison belonging to the chemical group of dioxyphenylalanine, which is of course closely related to tyrosine, one of the normally occurring amino acids of the body. He felt that this pellagra toxin, the "dopa" of the late lamented Bruno Bloch, came from beans. Perhaps dear old grandmother was not so far wrong on insisting "that we take our regular spring dose of sulphur and molasses."

There is yet another angle, however, to the question and that is the finding of Boggs and Padget,⁴⁰ Ramsdell and Magness⁴¹ and others that liver and liver extract are curative in pellagra. This curative action of liver preparations is probably related to their high content of vitamin B complex. What relationship liver extract or desiccated hog's stomach, which is also curative in pellagra, bears to sulphur and to cystine must await the researches of the biochemist.

Among the miscellaneous conditions in which we felt that sunlight was a factor in causation were two cases of lichen planus (fig. 7) and a case of multiple streptococcic furuncles which appeared rather rapidly after exposure to the sun and were sharply limited to the sunburned area.

SUMMARY

Evidence has been presented to show that disturbed sulphur metabolism plays a rôle in the production of light sensitivity and further that the exact status of the porphyrins in light sensitivity is as yet undetermined. The high incidence of lupus erythematosus following severe sunburn is recognized and certain cases will respond to dietary measures when all other known remedies have failed. Certain drugs, foods such as buckwheat, focal infections or physical allergy may at times be light sensitizing agents. Whether disturbed sulphur metabolism bears any relationship to vitiligo is yet to be discovered. What part faulty liver metabolism plays in the causation of actinic dermatoses and of pellagra is not known. It appears that liver therapy is of definite value in both conditions.

Sources of Vitamin A.—The chief sources of vitamin A are the livers of certain fish and mammals, dairy produce from well fed animals, eggs and animal fats. Carotene is found in yellow root vegetables, green leaves and many colored fruits and seeds. Vitamin A concentrates are made chiefly from the liver oils of fish and mammals, the liver oil of the halibut being one of the richest sources known.—Colwell, S. RAGWEED DERMATITIS

A REPORT BASED ON EIGHTEEN CASES

LOUIS A. BRUNSTING, M.D.

AND

C. RUSSELL ANDERSON, M.D.

Fellow in Dermatology, the Mayo Foundation

ROCHESTER, MINN.

Sensitivity to the ragweeds (Ambrosiaceae) is generally regarded in terms of the well known hay fever and asthma, which occur so commonly in the United States during the season of pollination in the late summer and autumn months. Occasional cases have been reported, however, of a recurring, eczematous eruption in this same season, in the form of dermatitis venenata affecting chiefly the exposed surfaces of the body, due to an acquired sensitivity of the epidermal cells to the irritating oil of the plant as distinguished from the manifestations of allergic reaction to ragweed protein.

In this agricultural belt of the Midwest, it has been our experience to encounter rather frequently this form of dermatitis, related to season and environment, particularly among farmers and others whose residence, occupation or other contacts bring them extensively into rural districts where ragweed is abundant. A growing interest in problems of sensitivity and a more generous application of the patch method of diagnosis enabled us, during the season of 1933, to identify and study eighteen cases of dermatitis due to ragweed; the cases form the basis of this report.

LITERATURE

The first systematic reports of dermatitis caused by ragweed were those of Hannah¹ in 1918 and of Sutton² in 1919. Others³ have commented on the frequency of a similar summer eruption associated with contact to weeds and dust in general and ragweed in particular.

The value of the patch method of testing these eczematous eruptions was brought out by Sulzberger and Wise,⁴ who in 1930 reported the case of a man, aged 40; in his case tests by the usual scratch technic gave negative results, but after application of the pollen to the skin for twenty-four hours under a patch there was a positive eczematous eruption.

Milford,⁵ and Brown, Milford and Coca⁶ subjected plants of ragweed to extraction in Soxhlet's apparatus by means of petroleum ether and anhydrous ethyl alcohol and found that the oily fraction so removed

was capable of provoking a positive patch reaction in a case of ragweed dermatitis and was to be distinguished from the atopic excitant or protein fraction that remained in the plant. On the basis of these observations it was recommended that measures of desensitization toward contact dermatitis to ragweed be carried out by means of the oily fraction of the plant. Pascher and Sulzberger⁷ mentioned a case in which treatment was carried out by this method; the patient was given intracutaneous injections of diluted oil of ragweed, which provoked a flare up at sites where positive patch reactions had been obtained five months previously.

There are few reports of sensitivity to burweed marsh elder⁸ (*Iva xanthifolia*), although the plant is a species of ragweed, is widely distributed in the middle

had several attacks of dermatitis, the onset can usually be dated to a definite week in July or August, which in itself is an important clue to the nature of the irritating agent. Symptoms are well under way by August, reach their maximum in September, and subside gradually within a few weeks after the first frost, which agrees fairly well with the season of pollination of the ragweeds. Periodic flare ups may occur after intimate contact with the plants themselves, after hunting trips, after weeding in the garden or fields, or after handling hay or grain that has become contaminated with the irritant. Five of our eighteen cases will be abstracted here:

ABSTRACT OF CASES

CASE 1.—A man, aged 49, a resident of northern Minnesota, an iron ore miner, farmed a small plot of ground at the edge of town. Each year, from 1928 to 1933, dermatitis of the exposed surfaces of the face, neck and forearms had developed, which had begun regularly in July and had subsided some time in October. The symptoms had been aggravated on windy days during this period, and in particular after he had worked on the farm plot.

CASE 4.—A man, aged 74, a farmer and dealer in farm machinery in a small town in Michigan, first had noted dermatitis of the face, neck and arms in July 1930, which later had spread to the trunk and legs and had persisted almost continuously until he came to the clinic in July 1933. During January 1932 the skin had become clear while he was confined to bed with influenza; on another occasion the condition had cleared after a visit to Ohio.

CASE 10.—A man, aged 56, a railroad section hand in Missouri, reported the occurrence of attacks of dermatitis during the autumn of 1932 and of 1933. Although the symptoms had improved in the interval, he had nevertheless been subjected to episodes of pruritus after days of work along the road bed. There had been a brief attack of dermatitis in the autumn of 1926. During the summer of 1933 symptoms were unusually severe, and the dermatitis had extended from the face and hands to involve the entire surface of the body, with considerable lichenification (fig. 1).

CASE 14.—A man, aged 28, a photographer in a small city in Minnesota, had dermatitis of the exposed surfaces of the face, about the eyes, for the first time in July 1933. The condition had persisted, with periodic flare ups and remissions, until October (fig. 2). In the spring of the same year he had taken up his residence in the outlying suburbs, where there was a luxuriant growth of ragweed in the adjacent fields. On one occasion, after symptoms had appeared, there had been a severe exacerbation, with edema of the eyelids, and dermatitis with intense pruritus of the face and neck, which had occurred within twelve hours of a long drive through the country. Shortly before, he had coated his face with a bland ointment, which apparently served to catch the irritating pollen dust in a most concentrated form. That the ointment itself was not the irritant was proved by subsequent tests. There was a definite familial strain of allergy in the form of hay fever and urticaria, and the patient himself had had hay fever caused by ragweed annually since 1929. He had received injections of ragweed protein for purposes of desensitization during 1930, 1931 and 1932, with benefit as regards the hay fever.

CASE 18.—A woman, aged 65, residing in a large city in Michigan, first seen in the autumn of 1933, during each autumn from 1914 to 1923 and again from 1931 to 1933 had suffered from dermatitis of the exposed surfaces, which had begun during the latter part of July and had lasted until October or November. Patch tests were positive to the ragweeds and to pyrethrum. Of interest was the relationship of the attacks to change of residence. During the first period, 1914 to 1923, she had lived adjacent to a baseball park that was overrun with weeds. She then had moved to a larger city thirty miles away and had been free from trouble until 1931, when she had moved from the settled districts of the city to a home in the suburbs, where there were many weeds nearby.

Fig. 1 (case 10).—Ragweed dermatitis, late stage, with lichenification of the skin.

Western and Southern states and, according to Durham,⁹ is a likely source of irritation.

CLINICAL COURSE AND SYMPTOMS

The clinical course of dermatitis due to sensitivity to weeds of this type is almost sufficiently clear cut to be pathognomonic. One of the most striking features is the tendency to seasonal recurrence each year. The reaction of the sensitized person depends in each case on the degree of sensitivity and the amount of exposure to the irritant. In the northern states of the Middle West there is sufficient dust in the wind in early summer to cause symptoms of pruritus among persons who are particularly responsive; however, if most of those have

Most farmers are exposed to the dust of ragweed the year round, through contact with clothes on which the dust has settled, or in the handling of hay or grain in the barns. If the involvement at first has been strictly seasonal, the condition may lapse irregularly through the winter months. It is probable also that in the more

Fig. 2 (case 14).—Ragweed dermatitis, early stage. The involvement of the eyelids is especially noteworthy.

extensive and resistant cases the reactivity of the skin, at first limited to the ragweeds, may become extended over a wider range of irritants, including pyrethrum,¹⁰ turpentine and other vegetable oils.

The earliest signs of dermatitis of this type are redness and edema of the tender skin of the eyelids and neck, with considerable pruritus. The exposed surfaces are chiefly affected, the face, the neck above the collar line, the hands, forearms and ankles. In most instances the dermatitis persists in the subacute stage, with erythema and superficial desquamation, and a minimum of vesiculation. The irritant may be spread to other parts of the body by the hands or clothing, or by the injudicious application of greases, during the early stage of contact. With continued exposure, the eczematous manifestations become more chronic, with lichenification and fissuring. In some cases only the eyelids are involved; in others, the eruption may be universal.

Evidently, sensitivity to ragweed is acquired only after long contact with the irritant, which is shown by the fact that of the cases reported elsewhere, as well as of those in this series, all patients were adults. The

youngest patient was 28 years of age, the oldest 74. The average age of those in this series at the time of the onset of symptoms was 42 years, and in the average of the group there was a history of recurrent attacks for almost six years (fig. 3).

The condition would naturally be expected to appear among persons who have extensive rural contacts, but it is not limited to farmers. However, there was only one woman in the 1933 seasonal group of eighteen cases observed. In none of the cases had the exact nature of the irritant been ascertained previously, although in general it was naturally suspected to be related to the dusts of the environment.

REACTIONS TO PATCH TESTS WITH RAGWEED

Although it has been demonstrated that the irritant in ragweed exists in the oil or oleoresin, which is most abundant in the leaves, there is certainly a sufficient amount of the irritant in the pollen to produce a reaction in the sensitized skin. In most instances of ragweed dermatitis the symptoms coincide with the season of dissemination of the pollen by the wind; they are aggravated by a dust storm and relieved after rain. On two occasions we subjected samples of ragweed pollen to a process of extraction with alcohol and ether in a Soxhlet apparatus for more than a week without being able to wash out all the irritant. When ripe, unwashed pollen is applied to the skin, a positive vesicular reaction is obtained in cases of the sort considered

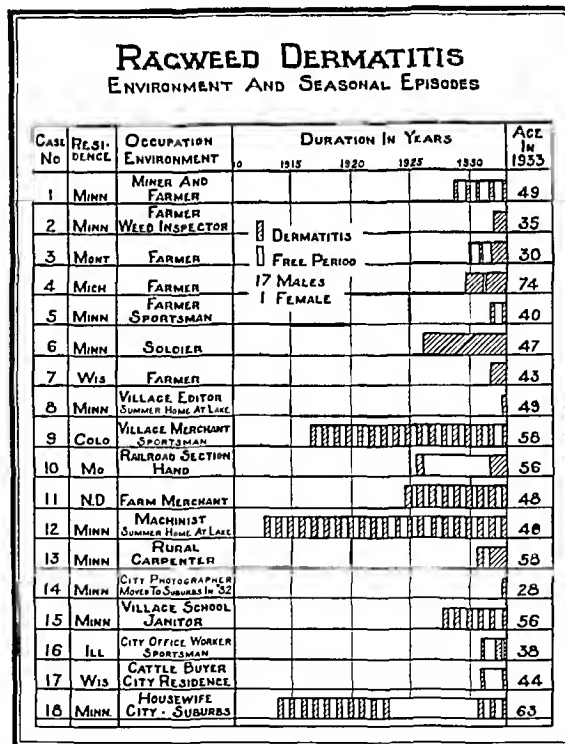

Fig. 3.—Place and season. Reproduction of wall chart.

here, which compares favorably with that provoked by the leaf or stalk of the plant. Pollens in this form are less expensive than the prepared commercial oils and are conveniently available at all seasons for patch testing.

When contact sensitivity of this type is suspected, the patient is tested by the patch method for sensitivity to

10. Feinberg, S. M.: Pyrethrum Sensitization: Its Importance and Relation to Pollen Allergy, *J. A. M. A.* 102:1557-1558 (May 12) 1934. McCord, C. P.; Kulker, C. A.: Pyrethrum: Etiologic Factor in Vasomotor Rhinitis and Asthma, *J. Allergy* 1:149-155 (Jan.) 1930.

the more common weeds and cultivated plants in harmony with the environment, as well as to such miscellaneous irritants of unlimited number as may pertain to the problems of the particular case in hand. In the case of the weeds, a small amount of the pollen is placed on a square of cloth that has been slightly moistened with olive oil and applied to a clear site on the skin, fixed with adhesive tape or bland cement for approximately twenty-four to forty-eight hours. A positive reaction is manifested by pruritus and the appearance of varying degrees of eczematoid change at the site in the form of erythema, edema or vesiculation (fig. 4). In very sensitive persons the patch should be removed and the site cleansed with alcohol at the first sign of irritation in order to avoid an uncomfortable reaction and a possible systemic flare up at all the sites of dermatitis, which sometimes occur.

Because of the wide distribution in the United States of the various species of ragweed, our tests on these patients included samples of several common species in each case in order that we might determine evidence of specificity of reaction to the genera as a whole or to

Fig. 4 (case 3)—Patch reactions in a case of ragweed dermatitis: a, positive reaction with Western ragweed pollen; b, Positive reaction with burweed marsh elder pollen, c, positive reaction with short ragweed pollen, d, negative reaction with turpentine, e, negative reaction with pyrethrum.

any single species or variety. The following specific weeds and miscellaneous irritants were used in sufficient number to indicate the trend and range of sensitivity: short ragweed (*Ambrosia elatior*), giant ragweed (*Ambrosia trifida*), western ragweed (*Ambrosia psilostachya*), burweed marsh elder (*Iva xanthifolia*), cocklebur (*Xanthium canadense*), pyrethrum (used extensively as an insecticide), turpentine, potassium arsenite (1 per cent solution), quinine sulphate (1 per cent solution) and corrosive mercuric chloride (0.1 per cent solution). The reactions to the patch test were graded in severity from — to ++++ and are recorded for the eighteen cases in this series in figure 5.

Inspection of figure 5 reveals the fact that almost all the positive reactions occurred within the range of the samples of ragweeds, particularly to tests with burweed and with two of the three varieties of *Ambrosia*, short and western ragweed. Cocklebur gave a decided reaction in only two instances and giant ragweed in only one case. Except for these two there is definite evidence of species specificity in the list of positive reactions. Our data in regard to other species are incomplete; in future testing it might be well to include other members

of the family of Compositae, such as the sages and heleniums,¹¹ which are also recognized as irritating weeds.

In four cases sensitivity was demonstrated to a single species or variety of ragweed (cases 1, 7, 8 and 16). In the other cases the reactions were polyvalent. The response to applications of samples of pyrethrum and turpentine is of interest (cases 4, 13, 17 and 18). In these cases the symptoms of dermatitis might well be expected to extend beyond the season of ragweeds, provided there was sufficient contact with paint or with insecticides, such as fly sprays or insect powders, which are now in common use and which contain pyrethrum.

The report in figure 5 on the reactions to giant ragweed is not in harmony with our expectations. It is likely that this particular variety is less irritating than the others, for it is not rare by any means and the samples that were used for testing a number of the patients included not only pollen from varied sources but also the leaf of the plant and the extracted oil. Detailed tests were made on one patient (patient 14) and on another patient sensitive to ragweed whose case is not included in this report; multiple samples of ragweeds from varied sources were used to demonstrate that the sensitivity in some cases may be restricted to certain varieties of the same species of ragweed, which will be reported subsequently.

In these cases, definitely positive reactions were not obtained to tests made with solutions of the metallic salts of mercury and arsenic. More data are needed in this regard before it can be said that a specific sensitivity exists in the skin to vegetable oils on the one hand and to metallic salts on the other.

Brown, Milford and Coca stated that, in general, 15 per cent of the average run of persons, whether normal, atopic or those with other forms of contact dermatitis, will give positive reactions to patch tests of oil of ragweed. At present we are attempting to confirm these interesting observations.

RELATION OF RAGWEED DERMATITIS TO ATOPY

Contact dermatitis to oil of ragweed is to be distinguished from the state that exists in hay fever and asthma when there is an urticarial response, on skin tests, to the protein fraction of ragweed. The latter condition reveals a familial strain and the presence of specific atopic reagins in the circulating blood, which can be demonstrated by passive transfer and which has not been satisfactorily demonstrated in contact sensitivity.

Scratch or intracutaneous tests with water-soluble protein allergens of ragweed were made in thirteen cases, and in only two was there a positive urticarial flare (cases 14 and 16). Atopic reagins to ragweed were demonstrated in both these cases; in one there was evidence of hay fever and an allergic familial strain; in the other, tests by the direct method and by passive transfer were likewise positive for ragweed and for orris root, without clinical history or familial record of the usual allergic manifestations, representing an example of incipient or undeveloped atopic capacity. This coincidence has been recorded on three other occasions.¹² One other patient (patient 6) is worthy of

11 Balyeat, R. M., Rinkel, H. J. and Stemen, T. R. Contact Dermatitis (Venenata) Distribution and Importance of the Heleniums as a Cause of Contact Dermatitis in the United States, *Am. J. M. Sc.* 184: 547-555 (Oct.) 1932

12 Hannan¹, Ramirez and Eller², Sulzberger and Wise⁴

mention in this regard. There was clinical evidence of vasomotor rhinitis and disseminated neurodermite with positive tests to foods by direct and indirect methods, but no reaction to ragweed protein, although there was superimposed dermatitis venenata during the ragweed season, with positive patch reactions, as recorded in figure 3.

In two instances of contact sensitivity to ragweed (cases 10 and 17), tests to ragweed protein were negative by direct application and by passive transfer, which is consistent with contact dermatitis in general. In a few persons who were tested by the scratch method to ragweed pollen, we observed dermatitis at the site of the tests about three or four days later, although there were no urticarial reactions immediately, which we interpreted as contact reaction to the oil in the pollen, which had been insufficiently cleansed from the skin after the tests. From a summary of these data, we are agreed that there is no more than a casual relationship between contact sensitivity and the atopic state.

TREATMENT

Symptomatic measures of treatment of ragweed dermatitis are similar to those recommended for dermatitis venenata in general. During the acute stages, the use of ointments and oily lotions is contraindicated, because they place the irritant in solution and favor its spread to unaffected surfaces. Wet dressings of astringents, such as lead acetate or aluminum subacetate, suitably diluted, are attended by considerable relief of symptoms. Soothing baths and drying lotions are likewise of benefit. During the process of involution there will be improvement under bland ointments, and sometimes fractional doses of roentgen rays may be given for relief of pruritus, but only under expert supervision.

An ideal method of escape is possible for those who are able to make a change of environment, which is admirably illustrated by the experience of one patient in this series (patient 18), who suffered dermatitis only when near weed-infested districts. Obviously, for the most part, such is not practical for the farmers who comprise the greater proportion of those who are sensitive.

In the earlier reported cases of ragweed dermatitis, treatment toward desensitization by means of injections of the protein-containing allergen was recommended with a favorable percentage of protection being conferred thereby. Others were not so fortunate, in particular a patient of Stroud and one in this series (case 14); in the latter case, dermatitis first developed after three years of such desensitization.

Brown, Milford and Coca, after pointing out that the contact irritant of ragweed was an oil, recommended that such specific oil be used by injection for purposes of desensitization. Favorable results have been reported¹³ by means of this method after other procedures had failed. Published reports are few, except in cases of sensitivity to Rhus, in which some observers obtained a decided elevation of the level of tolerance to the irritant, although the skin still responded with eczematous reaction to application of the specific irritant by the patch test. There is need for further controlled experiment in this field.

Our experience with the injection of specific oils of ragweed for purposes of desensitization is limited to

observations in eight cases in this series (cases 2, 4, 9, 10, 12, 13, 15 and 17), in which from three to six injections were given at intervals of from several days to several weeks during the time the dermatitis was in evidence. Injections consisted of 0.5 cc. of 1 per cent oil of mixed ragweed (short and giant) in sterile almond oil (Lederle) intramuscularly. In one case (case 10), oil of burweed was used. During the course of the treatment there was relief of symptoms in one case for twenty-four hours after each injection of the oil intramuscularly; in two others there was an associated flare up in the sites of dermatitis, and in the previous patch reactions, with increase in pruritus for a day after each injection.⁷ Two patients (10 and 17) expressed the opinion that the treatment by injection had served materially to shorten the present seasonal episode and to elevate to some extent the tolerance of the skin to previously forbidden contacts.

Observations of this type are difficult to evaluate, because it is the natural tendency of the hopeful patient to expect improvement, although at the same time he

unconsciously exerts a change in his environment by avoiding those contacts the irritating qualities of which have been pointed out to him.

The solution of oils to be used for desensitization should contain the various particular irritants to which the patient has been found sensitive. A comprehensive series of patch tests should be employed preliminary to treatment and at varying intervals afterward, in order to detect, if possible, any change in the degree of response of the reactive skin. The most practical manifestation of benefit from desensitization, however, rests with those who, having had repeated seasonal episodes of dermatitis, are enabled to carry on in the same occupation and environment with comparative freedom.

During the spring of 1934, the patients of this series who have been willing to cooperate have been started on further treatment preseasonally, and their reactions at the time of the expected return of symptoms with the ragweed season will be observed with interest.

COMMENT

Ragweed dermatitis is more common than is generally supposed. In cases of recurrent eruption in the summer, patch tests should include samples of the several ragweeds, as well as pyrethrum and turpentine. Further

investigative work is necessary in experimental and clinical fields to determine the exact nature of the irritant, the factors concerned with the development of sensitivity, and the mechanism of desensitization

ABSTRACT OF DISCUSSION

ON PAPERS OF DR COCA, DR WHITE, DRs N. P. ANDERSON AND AYRES, AND DRs BRUNSTING AND C. R. ANDERSON

DR MARION B. SULZBERGER, New York. The differentiation between atopic and contact dermatitis seems to be of far more than theoretical importance. Consider the following four points: 1. The difference in the test technique that must be employed. In contact dermatitis, the contact or patch test, in atopic dermatitis, scratch or intracutaneous tests. 2. The difference in the causative agents. In contact dermatitis, simple chemicals such as solution of formaldehyde, mercury and nickel salts, local anesthetics, dyes and plant oils, such as ragweed oil, primrose and chrysanthemum oils, and the fungi—I think the eczematogenous fungi of the monilia trichophyton group must be included in this series of irritants. In atopic dermatitis on the other hand, the so-called protein antigens, those which are the usual causes of other atopic diseases, are usually the causative factors. 3. The difference in the type of treatment in these two groups. In contact dermatitis, simple antipruritic measures, provided contact can be avoided, are usually sufficient. In atopic dermatitis perhaps because the avoidance of the excitants is more difficult, systemic measures have to be employed such as sedatives and more attention in general must be paid to the systemic treatment of the atopic dermatitis from the endocrinologic, the vasomotor and the psychic points of view. Needless to say, local and topical remedies, including x-rays, maintain their importance in the treatment of atopic dermatitis. Elimination diets combined with the removal of suspect inhalant substances and of foci of bacterial and/or mycotic infection should bring relief in many heretofore intractable cases of atopic dermatoses. Unfortunately, this procedure is in most cases practically impossible. I am not quite as pessimistic as Dr. Coca about the possible success of desensitization treatment with protein extracts in these cases though I admit that the desensitization is certainly much more difficult than either in the plant-oil group or even in the case of dermatomycoses, which in some selected cases certainly are markedly benefited by the combined injection of fungus extracts as Dr. Coca has stated. 4. The fourth difference is one that cannot be considered proved but must be considered only as a hypothetical possibility as yet. It is recognized that in contact dermatitis the epidermis is the shock tissue and the site of primary reaction. On the other hand, it appears probable that in atopic dermatoses the uppermost vascular layers of the cutis are the shock tissue. In other words, not the ectodermal but the mesodermal part of the skin is the "shock organ," and the epidermis becomes only secondarily affected, owing to repeated subclinical reactions in the upper cutis. This would seem to explain to some degree why atopic dermatitis is associated with vascular sensitivity of other organs as in hay fever and asthma, and the presence of urticarial skin test reactions and of reagins. It is amazing that one has such marked success with desensitization of a contact dermatitis in the case of the employment of the vegetable oils. All know how well nigh impossible it has been to desensitize cases of contact dermatitis due to substances other than plant oils. In view of these sharply contrasting results I believe it would be well to attempt desensitization with other substances with a method paralleling as closely as possible that employed in the cases of dermatitis due to plant oils.

DR JEFFREY C. MICHAEL, Houston, Texas. Dr. N. P. Anderson and Dr. Ayres have done valuable work in correlating and evaluating the knowledge on photosensitization and on photosensitive dermatoses. They have divided their paper into a consideration of the physical and biophysical properties of light and of photosensitization and then into a clinical discussion of the subject. As to the biochemistry and biophysics of light that pertain to cutaneous medicine probably every one

realizes that present knowledge is quite elementary and that it cannot be applied to clinical phenomena with entire satisfaction. The authors especially discussed the question of sulphur metabolism as it relates to light sensitivity and of hematomorphyrin. Of course there are many other substances that have photosensitive properties, among them two important circulating metabolites, sugar and urea. Sugar, I think, is quite an important photosensitizer, at least it has been suggested that the frequency of cataract in diabetes is due to the photosensitive properties of the sugar. I will discuss lupus erythematosus and pellagra together. I have seen cases of lupus erythematosus that have followed severe sunburn. The cases that I have seen are few, and all of them have occurred de novo. I am not so certain, however, that this is true photosensitivity. I do not think that such a precipitation necessarily indicates a true sensitivity. It may indicate a sort of biotropic effect. For example, cases of lichen planus as well as cases of psoriasis in which irradiation is done during the stage of progression of the disease will sometimes present lichen planus or psoriasis in the areas that have been subjected to x-rays just as in the case of Anderson and Ayres in which lichen planus had been treated with light. This is what probably occurs in these cases of lupus erythematosus and also in pellagra, in other words they are in a stage of the disease in which some further insult, in this case light, causes a precipitation of the disease at certain exposed points. If it should be conceded that this is true photosensitivity, it would be necessary to show that in these cases the skin is more fluorescent than it formerly had been and so far as I know such a condition has not been demonstrated. On the other hand, hydroa estivale and urticaria and eczema solare seem to be more specifically light sensitive cases. So far as urticaria is concerned, Wucherpfennig thought it well to divide cases of light sensitive urticarias or light allergic urticarias into two types, urticaria solaris meaning that they are precipitated by visible light and those which he calls urticaria photogenica, which are produced by invisible light.

DR JAMES R. DRIVER, Cleveland. Dr. Coca has actually thrown the challenge to dermatologists to give this subject the importance it deserves. The interest shown here will do much to keep certain phases of allergy in the specialty of dermatology where they belong. Drs. Brunsting and Anderson have called attention to a type of sensitization dermatitis that is doubtless much commoner than has been supposed. The fact that in the series they report there was only one woman affected is most interesting. One would expect the incidence to be higher. Farmers, of course, come in contact with ragweed the year round but naturally more so in the late summer months. The higher incidence at this time is to be expected. However, I believe that the presence of moisture on the skin due to perspiration is the factor that increases the possibility of irritation from the pollen. This is frequently seen in cases of fur dye dermatitis. As long as the fur and skin are dry no irritation results, but if the fur is worn in the rain, in a snow-storm or on a warm day, a dermatitis may occur. Dr. White has given some important facts in regard to some cases of acne. Every dermatologist has had cases that did not respond to the usual roentgen treatment but in the past the value of diets has been underestimated. Investigation along these lines is indicated in all cases of acne that do not respond to roentgen treatment within a reasonable time. It should be kept in mind however, that children under 18 years of age with acne do not respond well to roentgen treatment. Failure to recognize this fact has resulted in many instances of too much irradiation and the consequent unfortunate results. The rational use of diets along with roentgen treatment in acne cases should in many instances reduce the amount of irradiation necessary.

DR ALBERT H. ROWE, Oakland, Calif. I would emphasize cases of dermatitis that I have studied in California characterized by negative reactions to pollen oils but by definite reactions to pollens by the scratch or intradermal tests. These cases give a seasonal history. The eruption first appears on the exposed areas of the body, especially the face, hands, arms and legs but as the season progresses it gradually may involve more and more of the extremities and body. A few patients fail to react to pollens or to pollen oils but respond to treat-

ment with the important pollens in the air at the time of the dermatitis. Those patients who give positive pollen tests require antigens prepared according to their skin reactions. Treatment has to be given over long periods and perennial treatment is of as much value in obtaining permanent results as it is in the problem of hay fever. In California and also in the Middle West, Amaranth, Atriplex, Artemisia and other fall pollens, as well as ragweed pollens, must be recognized according to locality as the causative factors. Dr. Cleveland White's confirmation of the frequent occurrence of the acneform type of dermatitis due to food allergy is timely. Because of the difficulty in obtaining satisfactory skin tests in all food sensitizations, I have recommended "elimination diets" since 1928. These diets must be modified by skin reactions that are obtained, and history of food idiosyncrasies. The chosen diet must be used for one to three weeks in order to eradicate the allergic effects of former foods, and, if relief is not obtained, other elimination diets must be tried before food allergy can be ruled out. My experience indicates that manifestations of food allergy may recur in a few minutes or days after the resumption of a causative food, although such food may frequently be taken for two or three weeks, or even a month or two before established tolerance is overcome, and a return of the specific reaction, whether migraine, asthma or dermatitis, occurs.

DR. C. M. STROUD, St. Louis: I agree with Dr. Sulzberger that allergists should maintain a well balanced dermatologic outlook if they expect to treat patients who suffer with what seems to be an allergic skin disease. It is not always easy to differentiate allergic conditions from conditions that are entirely foreign to allergy; it is likewise not always easy to differentiate contact dermatitis from atopic eczema. The presence of atopic eczema should not deny the existence of a contact dermatitis. I have seen the two occur in the same individuals on several occasions. The presence of other allergic manifestations, such as hay fever, asthma or migraine, does not deny the existence of a contact eczema. For three years I have treated some cases of contact dermatitis with various oils, to which they showed reactions. I have given ragweed oils through three seasons as treatment. I have given pyrethrum oil and have also treated patients with turpentine and almond oil and have secured in most instances very desirable results. I agree with Drs. Brunsting and Anderson that some patients are sensitive to the oil of the short ragweed and not to the oil of the giant ragweed. I have found variations in their reactions on several occasions. Multiple sensitivity is common. Patients who have a contact dermatitis lasting the entire year have been noted to be sensitized to two or more substances acting as the causative factors in different seasons. Thus, a patient who had a ragweed dermatitis in the summer also had a lesion in the winter which appeared to be similar to the one in summer. The winter dermatitis was markedly improved when contact with wool was restricted. It is noted that allergy frequently complicates dermatologic conditions. It is probable that a few patients whom I have seen whom I considered as having an acne complicated by allergy, have in reality the condition that was mentioned by Dr. White. I have seen several patients who had acne who were not benefited by dermatologic procedures until various substances to which they showed positive allergic reactions were removed from their environment or from their foods. A carefully taken history frequently gives important information regarding the causative factor and thereby reduces the number of necessary tests to a minimum.

DR. G. L. WALDBOTT, Detroit: Urticaria is often caused by pollen. This has been clearly brought to me during the past year when at the height of the tree hay fever season a large group of patients came to my office with hives. At the same time, several pediatricians called me up and wanted to know "what was in the air," because they had the same experience. Some of these patients had nasal catarrh, and injections with tree pollen extracts gave them considerable relief within one to two days. In some, the condition cleared up a week or so after the pollen had disappeared from the air. If one remembers that the majority of investigators believe that pollen is the most important single cause in allergy, one will appreciate its rôle in allergic skin diseases. Another point concerns the question of acne. Various types of skin lesions are

referred to the allergists. Sometimes the patients come on their own initiative with the desire to be skin tested. I have been in the habit of referring such patients to dermatologists whenever I thought that I was dealing with a nonallergic disease. However, once an acne patient insisted on the tests. She had a negative family history and there was no evidence whatever of allergy. After certain foods to which she gave positive reactions had been eliminated and a few desensitizing injections of inhalants had been given, the patient's acne, which had been present for a long time, disappeared. Since then I have given these cases at least the benefit of an allergic investigation and have found it well worth while. As to the question of food sensitivity, I should like to discourage some of the enthusiasm expressed by some of the previous speakers. I feel that food is an important factor, but its control is not the panacea of treatment of allergic diseases. In my hands, elimination diets have not been very successful. If one considers that any inhaled antigen can be demonstrated by immunologic methods in the blood soon after the inhalation, one will probably pay more attention to pollen and other inhalants and obtain better results. This also explains why dermatologists have had such poor results in desensitizing eczema cases with food extracts, since the food that is employed in the treatment is not the main causative agent. If one determines correctly which of the many causative substances is the main factor, and if one treats the patient with this specific extract in small increasing doses, whether it is food, pollen or epidermal, there will be less pessimism concerning desensitizing eczema cases in the future than there has been in the past.

DR. A. B. LOVEMAN, Louisville, Ky.: I should like to ask Dr. White whether routine gastric analyses were made in his cases. Within the past four months I have had ten or twelve cases similar to those described, which were most resistant to the usual type of therapy, which included x-rays, ultraviolet rays and a low carbohydrate diet. Gastric analyses were made because of the resemblance of this type to acne rosacea. In about 50 per cent of the cases I was unable to demonstrate any free hydrochloric acid, and in the other 50 per cent, although some free hydrochloric acid was present, there was a definite hypo-acidity. They all improved markedly on hydrochloric acid by mouth. Incidentally, all the cases to which I refer were in girls and were the erythematous type, clinically simulating features of both rosacea and iododerma.

DR. LEON UNGER, Chicago: Dr. White quoted a case of mine of a girl of 13 whose acne was incidental to her main complaint, which was one of epileptiform convulsions due to epilepsy. The mother mentioned that eating eggs caused a rash. We took eggs out of the diet, the acne disappeared, and the epileptiform convulsions disappeared and have not recurred in the last seven or eight years. It is well known that certain other foods, such as strawberries, will cause acneform rashes. Many people get pimples instead of getting hives from eating strawberries. I agree with Dr. Rowe that the skin tests in the cases of acne due to allergy should be done. While the skin tests may not be positive, they will be of great help if positive, as it is a short cut to diets. I should like to ask Dr. Coca about the source of his oil fractions; whether they are made from the pollen, stalk or leaves, and a little more detail about the injections of the oil extract. Drs. Brunsting and Anderson's observation that these patients give strongly positive contact tests with the short ragweed and negative contact tests with giant ragweed brings up an interesting point. I have always thought that giant and short ragweed were practically identical, and in hay fever patients one can give an injection of a certain dose of giant ragweed and can shift him over to an equal dose of the short ragweed without any constitutional reactions. It would seem, therefore, that as far as the ordinary allergy as expressed in hay fever and in asthma is concerned there is an identical element in short and giant ragweed but that the two differ greatly in their oily fractions.

DR. JOSEPH MULLER, Worcester, Mass.: Concerning the deductions of Drs. Anderson and Ayres, I want to ask whether they are familiar with the chemical work done by Professor Bloch of Zurich, his pupil Professor Rothman of Heidelberg, now of Budapest, and Dr. Rajka of Budapest, who investigated

other amino acids and obtained important results. I don't see that their paper produces evidence that those conditions which are light sensitive are due entirely to the source mentioned. Rajka also demonstrated some changes in the enzymes of the skin under ultraviolet irradiation. Dr. White apparently differentiates between acnelike dermatoses and true acne. I was working in a similar field and I want to bring out some clinical differences between true acne and the acnelike dermatoses. The general appearance of the skin of these patients is rather a dry one and not the extremely oily one of the true acne vulgaris. The eruption, as Dr. White mentioned, was mostly nodular or papular, and there was much less suppuration than in true acne. The forehead is more often affected than is the case in true acne. I had the same experience with the elimination diets as Dr. Rowe. I had excellent results. I never could get any positive scratch tests in these acnelike cases. In a small number of cases I made hydrochloric acid determinations and in some of the cases which I thought were not acne but an acnelike eruption I got very low hydrochloric acid values. About 30 per cent of them improved on hydrochloric acid alone, without any allergic work being done on them. The rest of them were cleared up by elimination of certain foods from their diet, and in a great number of them I could get a relapse within a week by allowing the patients to eat again the allergenic food.

DR. SAMUEL M. PECK, New York. I disagree with both Dr. Coca and Dr. Sulzberger in their conception of what they call atopic eczema, not in its entirety but in some of its manifestations. Dr. Sulzberger carried the conception of atopic eczema into its clinical phase and has brought into that group what is generally called disseminated neurodermatitis and furthermore he has differentiated the shock tissue or the point at which the allergic action takes place, by saying that unlike contact dermatitis it is not mainly in the epidermis but mostly in the upper vascular layers and the papillary body. If one studies a group of children with eczema over a long enough time it is striking that children with typical neurodermatitis disseminatus practically all have had an infantile eczema and yet one practically never sees this clinical picture during the first year of life. In other words, a clinical picture that resembles ordinary eczema with vesiculation, scaling and crusting without any special arrangement of predilection (except the cheeks) invariably precedes the typical lichenified neurodermatitis picture in the flexors. About 90 per cent of those cases of eczema in which there is a hereditary family history of allergy (the atopic group) will develop into a typical neurodermatitis disseminatus after the second year if the skin manifestations last long enough. This observation is important in that such a differentiation would fit in with Dr. Coca's and Dr. Sulzberger's conception of atopic dermatitis in infancy and childhood, meaning by that that in the atopic dermatoses one is dealing with a tendency to manifest a neurodermatitis type. On the other hand, only 50 per cent of my neurodermatitis cases gave a family history of allergy when the patient was over 2 years of age. My observations have proved to me that in infancy there is no way of clinically differentiating the group that would eventually develop a neurodermatitis disseminatus. It is doubtful that in the neurodermatitis group or in the atopic group one is dealing with a mechanism and localization of the allergic manifestations that in any way differs from ordinary eczema. Routine testing of children with eczema for almost four years by means of the scratch and patch methods shows that scratch tests are of much less importance than the patch tests; furthermore, this statement applies equally to the neurodermatitis group. Contact or environmental substances were much more important than foods in giving positive reactions with patch tests. Foods were important in the infantile cases only. No matter what type of eczema was seen in infancy and childhood it is common knowledge that these cases invariably cleared up in the hospital. This seems to me an added proof of the importance of the environmental factor as against foods.

DR. HOWARD FOX, New York. I should like to say a few words about the diagnostic value of sensitization tests in skin diseases. In my experience both the scratch and the intradermal tests have been very disappointing, especially in atopic eczema, while on the contrary patch tests, especially in contact

eczema, have been extremely valuable. I am speaking not so much of personal experience as that of a group of men who worked for four years in my clinic at the New York University. This group consisted of trained allergists under the leadership of Dr. Aaron Brown, himself a pupil of Dr. Coca. Some twelve thousand tests were made, mostly by the intradermal method, which is acknowledged to be more sensitive than the scratch method. The diseases studied included, among others, eczema, urticaria, angioneurotic edema and erythema multiforme, most of the patients being adults. Innumerable reactions were obtained, the majority of which, however, appeared to have no practical significance. This was especially true of the intradermic tests for foods. I should like to say a word about a case which Drs. Anderson and Ayres mentioned, one of lichen planus apparently due to light sensitization. This I think is a rare occurrence, though I had a similar case of a boy who developed an acute generalized lichen planus following a violent sunburn, the eruption appearing on areas not covered by his bathing trunks.

DR. ARMAND F. COHEN, Louisville, Ky. I wish to record my observation that dermatitis occurs in a number of atopic patients during the grass as well as the ragweed season. This is explained by the fact that, when the epidermis is the shock organ, the epidermis will react in those allergic individuals who receive a sufficient amount of the excitant to which they are specifically sensitive. I make this statement because the impression may be gained that symptoms are produced only through contact with ragweed pollen or some portion of the ragweed plant. I have observed this dermatitis appearing in patients who get in contact with ragweed or grass only through inhalation. Such dermatitis may likewise occur through artificial injection. When the epidermis is the shock organ, regardless of how the excitant is introduced, the epidermis is the tissue that will react.

DR. ARTHUR F. COCA, New York. Replying to the discussers in the reverse order, I would say to Dr. Peck that I would like to see him alone sometime for an hour or two, and we will try to compose our differences. Dr. Unger asks what oil fraction is used in the treatment of ragweed dermatitis. I am using the oil extracted from the leaf of the plant because I have found this much stronger in skin test than the oil obtained from ragweed pollen that has been thoroughly dried and stored for some time. Under these conditions the oil in my leaf deteriorates rather rapidly and I suppose that a similar deterioration takes place in the oil of the stored ragweed pollen. This might explain why farmers have their ragweed dermatitis only in the summer time. The ragweed that they harvest with their other farm products lies open, exposed to the air, and it is quite possible that the excitant in this dry ragweed deteriorates and this is why they show no symptoms during the winter in spite of contact with the dry stuff. I think that it is quite probable that Dr. Waldbott is not right in his idea that pollen may produce urticaria. There are only two ways that I can think of by which urticaria could possibly be caused by contact with pollen by surface contact or by absorption through the mucous membrane. It is well known that surface contact with a protein does not produce urticaria, as a rule. On the other hand, if the possibility is considered of the urticaria being due to absorption of the proteins through the mucous membranes, there is almost experimental information about that. Urticaria does occur if an overdose of an aqueous pollen extract is injected, but it must be an overdose. One does not get constitutional symptoms from the inhalation of a few grains of pollen during the pollen season. Therefore, on a quantitative basis alone it seems to me quite unlikely that urticaria can be due to the natural contact with pollen. Dr. Rowe states that he has seen a group of patients that were not sensitive to contact with the oil of pollen but were sensitive to the scratch test, and he considers that the oil in these cases was not the excitant of the contact dermatitis. Here there is a conflict with the principle of the separation of the atopic group from the group of contact dermatitis or epidermal allergy. Contact dermatitis is not produced by the water soluble extracts or substances in plants and the intracutaneous test with the oily excitants of it results negatively. This can be considered an established principle. Therefore, if Rowe's patch test reaction to the oil was nega-

tive, I would rather look into the freshness of the extract or the method of the testing

DR LOUIS A. BRUNSTING, Rochester, Minn. I should like to say that the experiments we did with giant ragweed were controlled by samples of pollen that we obtained from six or seven sources over the country, and in the control cases we applied these samples without getting positive reactions so that when we reported a negative reaction we meant a negative reaction to more than one sample. I would take issue with Dr Coca that desensitization with the oil extract in contact dermatitis is usually successful. Dermatologists are not willing to say that for Rhus toxicodendron. Those who have had experience with the desensitization find that the results are extremely desultory. Furthermore, there is no list of data extant to show that the contact irritability of the skin after such injections has been materially reduced quantitatively, and in addition the injection of oil extracts is not entirely without harm. We have seen an exfoliative dermatitis produced in an undertaker who had eczema of the hands and face due to sensitivity to formaldehyde, in whom we injected a minute amount of diluted solution of formaldehyde intradermally. A certain number of patients, florists, for instance, some sensitive to pyrethrum and some sensitive to chrysanthemum, have not obtained uniformly good results by such methods. Rather than accept the oil treatment for general usage I would suggest that it be held *sub judice* pending further clinical trial before being used indiscriminately. I would say, with regard to the classification that has been put out didactically between contact dermatitis and atopic eczema, it appears that in a number of instances in contact sensitivity there is a family susceptibility to external irritants.

DR NELSON PAUL ANDERSON. Answering Dr Muller, I am not at all familiar with the work that he quoted. Regarding Dr Michael's suggestion that perhaps sugar metabolism plays a role in these cases, there is the observation of Urbach in a case of light sensitivity with hematuria. He treated this patient by means of a high carbohydrate diet and the injection of small doses of insulin, feeling that this relieved some of the stress on the liver. The whole question of liver therapy in light sensitivity needs to be looked into, whether it is due, as it probably is, to its vitamin containing complex or whether it is due to certain sulphur compounds is yet to be determined.

DR CLEVELAND J. WHITE, Chicago. As a group, dermatologists have not taken the study of diet very seriously, in fact, at times some have held it up as a subject of ridicule. Dr Sulzberger has sounded a timely warning in these acne-form cases in regard to a complete general examination. I am not convinced yet that diet is the cause of all these acne-form eruptions. I think it is of great value in many of them, but it is necessary to go further to see if there are not some endocrine changes, and so on. However the endocrine experts with whom I have talked have not all been able as yet to give much help. As Dr Driver has said, the most important thing is, if the patient's acne cannot be cured, to give him an x-ray burn in its place and still have some eruption persisting. I think it is extremely important to consider the dietary factors in many such persistent cases before too much roentgen therapy is given. Dr Rowe emphasized again the necessity of being on the right track and persisting in elimination diets for at least one, two or three weeks. The physician has to talk to these patients to see if they have been really on the diet, because oftentimes they will eat things that they consider in the diet. It takes a great deal of detective work to follow the dietary phase. Dr Loveman asked about the gastric analyses. There has not been one gastric analysis done in this group of cases. I think possibly the administration of hydrochloric acid may raise the allergic threshold to the foods to which the patient may have been sensitive rather than having any significant meaning as far as the hydrochloric acid contents of the stomach are concerned. Further study will be needed to confirm this impression. Dr Unger stated the desirability of doing skin tests in these patients. The tests should be persisted in, for occasionally they are very helpful. In this group of cases, the epidermal testing has been of very little aid in detecting the offending specific foods.

IMPORTANCE OF ALLERGY IN ETIOLOGY AND TREATMENT OF NASAL MUCOUS POLYPS

RICHARD A. KERN, M.D.

AND

HARRY P. SCHENCK, M.D.

PHILADELPHIA

In a previous communication we¹ presented evidence which in our opinion justified the conclusion that allergy is a constant factor in the etiology of so-called mucous nasal polyps. At this time we present further clinical data which we feel confirm our original view. It may be well at the outset to define the type of lesion to which we refer. Nasal polyps, other than malignant forms, may be classified as (1) mucous polyps or edematous fibromas (a better term we feel is myxoid fibroma), (2) mixed polypoid hyperplasia, and (3) papillary hypertrophy or mulberry polyps.

1. Mucous polyps or edematous fibromas (myxoid fibromas) may be single or multiple and are frequently pedunculated. They are smooth, pale and translucent, varying in color from translucent white or gray to bright yellow tinged with red. Older polyps may show marked discoloration. They possess a characteristic jelly-like softness and their consistency is such that unless palpated by a probe they may at times be mistaken for mucus.

Microscopically, hypertrophy and edema of the tissue from which the polyp has arisen are the striking features. Mucous glands may be lacking or present in scanty remains. The epithelium varies from a thin layer of squamous cells to a thick, many-celled layer of stratified columnar epithelium. Ciliated cells become increasingly rare in older polyps. The bulk of the polyp consists of an edematous tunica propria, with large areolar tissue spaces, containing a considerable quantity of albuminous fluid and showing a tendency to cyst formation. The areolar fibers are loosely disposed, crossing in all directions and enclosing correspondingly indefinite lymphatic clefts. The cellular constituents are relatively inconspicuous (fig. 1) and are bathed by the fluid which wells through the interfascicular spaces. Within these clefts are also lodged the migratory lymphocytes, round cells, plasma cells, mononuclear cells and eosinophils. The eosinophil content will be discussed farther on. When the process has extended deeply, an exostosis of bone may be present at the site of the polyp. This is by far the most frequent form of nasal polyp.

It is the mucous polyp that is the subject of our discussion.

2. Mixed polypoid hyperplasia, as Kaufmann² points out, is essentially similar in structure to the mucosa but is more markedly cellular. It is red or grayish red. This group may be subdivided into (a) glandular hyperplasia or glandular polyps, and (b) angiomatous polyps.

Glandular hyperplasia or glandular polyps, as described by Hopmann,³ are dense, vascular formations,

are usually red, and retain their form on pressure. Histologically, they differ from mucous polyps by being rich in glands and infiltrated with cells, and by having an exclusive origin from the turbinates themselves. By presenting a body separable from the mucous membrane and by being movable with a probe, they may be distinguished from hyperplasia following hypertrophic rhinitis.

Angiomatous polyps comprise a small group of highly vascular lesions of obvious characteristics.

3. Papillary hypertrophy or mulberry polyp is differentiated primarily by its papillary form. Appearing on the posterior end of the inferior turbinate, the mass consists of hyperplasia of the turbinal mucous membrane in which cystic degeneration of the glands and dilatation of the vessels have occurred. This type has by some been considered as a mixed or combination

Fig. 1.—Section of a typical mucous polyp under high power. The cells are inconspicuous, while edema of the tunica propria accounts for the bulk of the polyp.

form of glandular and angiomatous polyp mentioned in the preceding section. Its papillary structure, its usually red color and its comparatively firm structure readily differentiate the mulberry from the mucous polyp. Mulberry polyps are relatively infrequent lesions.

That true tumor formations may be frequently mistaken for mucous polyps is well shown in the following case:

A man, aged 56, had had nine operations in ten years for what were thought to be mucous polyps. At the tenth operation, six polyps⁴ were removed and the volume of tissue totaled 20 cc. Microscopic examination demonstrated this tissue to be a neurogenic tumor. Dr. Joseph McFarland, to whom we are indebted for the microscopic studies, suggests that the tumor arose from the terminal filaments of the olfactory nerve.

4. The tissue was obtained through the courtesy of Dr. T. Harris Boughton, Mercer Hospital, Trenton, N. J.

A detailed discussion of the theories that have been advanced as to the etiology of mucous polyps was presented in our earlier paper.¹ While various causes of mucous nasal polyps have been proposed and defended from time to time, not one has received complete acceptance. Polyps have been held to be the result of inflammation,⁵ infection,⁶ necrotizing ethmoiditis,⁷ sinus suppuration,⁸ vascular disturbances⁹ and lymph-vascular disease.¹⁰ Of these the inflammation-infection theory has heretofore been most widely championed.

A constitutional or hereditary factor¹¹ has been suggested from time to time since the earliest writings on the subject, largely, it would appear, in an attempt to explain the discrepancies between clinical observation and other theories of origin. More recently, Runge¹² has stated that in his opinion the development of polyposis demands the preexistence of a general pathologic alteration of the mucosa, the "hyperplastic mucosal constitution."

ALLERGY IN THE ETIOLOGY OF NASAL MUCOUS POLYPS

That the changes in the nose and sinuses in allergy are similar to those which occur in the bronchial structures in asthma has been pointed out by Hansel,¹³ but he was unwilling to admit an allergic factor in the etiology of all mucous polyps, notably in primary sinus infection with polyps. Hirsch¹⁴ has gone further, stating that it is his clinical impression that all mucous polyps may be based on allergy. Recently, Leroux and Delarue¹⁵ noted that every patient presenting polyps rich in eosinophils also had more or less characteristic allergic disease, and that in all patients with allergic disease and polyps, the polyps showed many eosinophils. Wiethe¹⁶ likewise regards allergy as the important

etiologic factor in the formation of mucous polyps and reports the disappearance of polyps in a patient following desensitization to an allergen.

We wish to present clinical data, obtained since the publication of our original paper, supporting the view that allergy is constantly a factor in the causation of nasal mucous polyps.

TABLE 1.—*Clinical Incidence of Mucous Polyps in Allergic States*

	Total Cases	Number with Polyps	Percentage
Bronchial asthma	600	183	30.5
Vasomotor rhinitis	104	15	14.4
Hay fever (seasonal)	118	16	13.5
Hay fever plus perennial asthma	52	18	34.6

The incidence of nasal mucous polyps is strikingly high in allergic diseases of the respiratory tract. The incidence is highest in those allergic states which continue throughout the year, notably asthma; it is lowest in pollinosis, the allergic disease in which the sensitizing substance acts on the nasal mucosa for only a few weeks each year.

The incidence of nasal mucous polyps is extremely small in patients whose presenting symptoms are those of nonallergic diseases. In studying the relation of paranasal sinus disease to diseases of the lower respiratory tract, as well as to diseases elsewhere in the body, we were struck with the infrequency of nasal polyps in connection with infectious states of the respiratory tract, especially in infection of the sinuses. In seventy-three cases of bronchiectasis, every one of which showed roentgenologic evidence of sinus disease and usually a pansinusitis with dense clouding of the affected sinuses, only a single patient had definite mucous polyps. It therefore seemed highly questionable to us that infection was the sole factor in the etiology of mucous polyps. We then determined to search out the incidence of mucous polyps in a large series of patients suffering primarily from nonallergic diseases and to investigate further from the standpoint of a possible unsuspected allergy those individuals found to have polyps. Of 372 patients with pulmonary tuberculosis as diagnosed in the Medical Division of the Hospital of the University of Pennsylvania, eighty-two gave sufficient evidence of nasal abnormality to lead to a clinical examination of the nose by a rhinologist. Mucous polyps were found in six. Yet forty-five of these patients, especially those with cavitation,

teen patients with lung abscess, all with extensive sinus disease, none had polyps.

We then attempted to study from the standpoint of allergy the fourteen patients who presented themselves for an obviously nonallergic disease and yet were found to have polyps. In one of these, a supposed polyp proved on section to be carcinoma. Of the other thirteen patients with polyps, ten were found to have asthma, one had asthma and vasomotor rhinitis and one had vasomotor rhinitis alone. The remaining patient, a youth, aged 17 years, with extensive bronchiectasis, gave a pronounced family history of asthma, vasomotor rhinitis and urticaria. At the age of 8 years he had had symptoms that had led an experienced pediatrician to make a diagnosis of bronchial asthma. When tested by us, the patient gave positive skin tests to house dust and feathers.

mixed infection and profuse sputum, had evidence of sinus disease, which in many instances was most extensive. Of 200 patients with chronic arthritis, in whom an intranasal examination was made in a search for focal infection, seven were found to have mucous polyps. Yet eighty patients were found to have sinus abnormality clinically or roentgenologically. Of seven-

DO NASAL MUCOUS POLYPS OCCUR IN THE ABSENCE OF ALLERGY?

In order to find the answer to the question whether nasal polyps occur in the absence of allergy we have been on the watch for all patients who presented themselves to the rhinologist simply because they had nasal symptoms associated with polyps and who did not complain primarily of any obviously allergic disease. These patients were carefully questioned as to allergic disease in themselves and in their families. Whenever possible, complete skin tests were performed and a polyp was removed for microscopic section.

In a careful search during more than a year we succeeded in collecting only twenty-five additional cases of polyps in which the patient had not complained primarily of an allergic condition. These twenty-five

ARTIFICIAL PNEUMOTHORAX

CLINICAL LECTURE AT CLEVELAND SESSION

J. ARTHUR MYERS, M.D.

MINNEAPOLIS

Itard coined the term "pneumothorax" in 1803 to designate the existence of air in the pleural cavity. He had observed three cases of spontaneous pneumothorax and made reference to the cases described by Selle and Boyle. Since that time large numbers of cases of spontaneous pneumothorax have been reported, particularly since the advent of the x-rays, and numerous references have been cited in the literature. Thus nature demonstrated that a lung may be partially or completely collapsed while the opposite lung carries on adequately the respiratory functions of the body. Moreover, observation revealed the fact that marked improvement of pulmonary disease sometimes occurs following spontaneous pneumothorax. These facts brought to light great possibilities in both the diagnosis and treatment of chest diseases.

After carrying out several experiments on animals, Carson, a Scotch physician practicing in Liverpool, in 1822 concluded that one lung can be collapsed artificially with safety by introducing air into the pleural space. Although he recommended that artificial pneumothorax be used in the treatment of pulmonary tuberculosis in man, he apparently did not administer it. Only a decade later, McRuer of Bangor, Maine, made some independent observations, which also led him to recommend immobilization of the diseased lung by introduction of air into the pleural cavity. In 1882 Forlanini of Italy also suggested artificial pneumothorax in the treatment of pulmonary tuberculosis.

Although there is reference in the literature to the introduction of air into the chest for the treatment of disease by the Greek physicians in the fourth century B. C., the modern practice of artificial pneumothorax dates back to 1888, when Forlanini introduced air into the pleural cavity of a patient suffering from pleural effusion, and in 1892, when he actually collapsed a diseased lung.

Apparently not knowing of the work of Forlanini and from independent observations and thinking, Murphy of Chicago reported some actual cases he had treated by artificial pneumothorax in 1898. Tice began to use artificial pneumothorax about the same time as Murphy, and Lempke continued the work that Murphy began. Since that time artificial pneumothorax has become a standard method of treatment. Waring speaks of it as a "procedure that has unquestionably saved hundreds of thousands of lives, and as long as mankind suffers from tuberculosis will remain a most valuable method of treatment."

METHOD OF ADMINISTRATION

In collapsing the lung by this method, pure nitrogen, pure oxygen, carbon dioxide and sterile air have been used. Although these gases in pure form may have

Prepared with the aid of a grant from the Medical Research Fund of the University of Minnesota Medical School.
Read before the General Scientific Meeting at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 11, 1934.
From the Departments of Internal Medicine and Preventive Medicine, University of Minnesota Medical School, and the Lymanhurst School for Tuberculous Children.

cases were gathered not only from the outpatient department of the Division of Otolaryngology of the Hospital of the University of Pennsylvania with a total number of 2,486 new patients and 6,225 patient-visits in the year, but also included several patients from the private practices of our colleagues who knew of our interest in such cases.

That so small a number was found is in itself good evidence of the rarity of nasal mucous polyps not due to allergy, if indeed they exist at all. In twenty-two of the twenty-five patients, a careful inquiry revealed a definite history of allergic disease, including asthma in

in the absence of hypersensitiveness of the individual, does not lead to the formation of typical nasal mucous polyps. To raise the question as to whether there is concerned a hypersensitiveness to inhaled substances only, or to bacteria only, or to combinations of the two is beside the point, although we admit all three possibilities in individual cases. The main point is, we believe, that hypersensitiveness of some type is present and operative in all cases of nasal mucous polyps. For a detailed discussion of the mechanism of allergy in these cases the reader is referred to our previous article.¹

Nasal mucous polyps represent a pathologic process in which regression to a normal state would appear extremely unlikely. The greatly overstretched mucosa, the poor blood supply and the easy compressibility of the slender pedicles of most of these lesions are obvious reasons against such regression. Yet we have seen typical mucous polyps disappear completely in four cases, merely after treatment of the allergic factor, and Wiehe¹⁰ has reported a similar instance. While it is of course not to be expected that mucous polyps will disappear merely by treating the patient for his allergy, nevertheless the fact that any case has been so cured has some value as evidence for the allergic etiology of these lesions.

The importance of making histologic studies of nasal polyps has not been sufficiently emphasized and the failure to make such a study has led to clinical error.

Fig. 3.—Mucous polyp removed after the first frost: Eosinophils have almost completely disappeared. Patient E. R.

thirteen individuals, hay fever in two, vasomotor rhinitis in thirteen, migraine in two and urticaria in one. Yet in none of these cases had allergic disease appeared on the record first submitted. In twenty there was also a definite family history of allergy. Positive skin tests were obtained in seventeen of the nineteen patients tested. Microscopic section showed typical mucous polyps in nineteen of the twenty cases so studied. There was only a single case in which there was neither a personal nor a familial history of allergy and with negative skin tests as well. Microscopic examination of the tissue removed from this patient showed that what clinically had been considered a mucous polyp was in reality glandular hyperplasia and therefore not of allergic origin. The question Do mucous polyps occur in the absence of allergy? we would still answer in the negative as far as our own experience is concerned.

COMMENT

With increased assurance we repeat our original view that probably all patients with typical nasal mucous polyps are allergic. Infection alone, that is, infection

Attention is called again to the patient who had ten operations for supposed mucous polyps but only after the last operation was a polyp sectioned and the true diagnosis of neurogenic tumor established. In one of our own cases, the supposed mucous polyps were twice removed before microscopic examination was made and the glandular hyperplasia recognized. It is now our routine procedure to study microscopically the material from all our cases of polyp.

At this point we would call attention to an erroneous interpretation that has been placed by a number of observers on a detail of the histologic structure of mucous polyps. We refer to the matter of eosinophil content. It seems to have been assumed that the presence or absence of eosinophils in mucous polyps represents a constant and unchanging feature of their structure. This has led to the view that those mucous polyps which contain many eosinophils have an allergic origin, whereas those with few or no eosinophils are therefore not of allergic nature. This view we are convinced is incorrect for this reason: Polyps removed from a hay fever patient during his pollen season show many eosinophils (fig. 2); polyps removed from the same patient only a short time after the pollen season is over show practically no eosinophils (fig. 3); yet pollinosis was the only etiologic factor involved. This observation we have made not once but a number of times. It is our opinion that the presence of many eosinophils in a polyp indicates recent exposure to the exciting allergen and, conversely, a paucity of eosinophils suggests that there has not been recent exposure to the allergen.

TREATMENT OF NASAL MUCOUS POLYPS

If it is true that allergy is a constant factor in the causation of mucous polyps, a search for and careful attention to the allergic factor becomes a prime requisite in the study and treatment of all cases of nasal mucous polyps. It is the neglect of the allergic factor that probably accounts for the great frequency with which mucous polyps recur after their operative removal. In polyp cases, therefore, careful sensitization tests should be a routine procedure. When possible, the reacting substances should be avoided; otherwise a thorough attempt at desensitization should be made. Of course, the correction of anatomic abnormalities, the adequate drainage of infected sinuses, the use of vaccines and suitable local treatment are integral and indispensable parts of the management of these cases.

CONCLUSIONS

1. Nasal mucous polyps are extremely common in allergic conditions of the respiratory tract.
2. Nasal mucous polyps are rare in patients with non-allergic diseases of the respiratory tract, even in the presence of extensive and chronic sinus infection.
3. In our experience, all patients with mucous polyps have been found to have either a personal history of allergy or a family history of allergy or positive skin tests and usually all three. No case of nasal mucous polyps has as yet been encountered in the absence of these three.
4. Histologic study of the tissue removed in polyp cases should be made as a routine procedure to guard against diagnostic error.
5. The eosinophil content of polyps may vary from time to time and is dependent on exposure to the causative allergens.
6. The finding of nasal mucous polyps in a patient warrants the assumption that the individual is hypersensitive, and the case should be studied from that standpoint.
7. The treatment of patients with nasal mucous polyps must include attention to the allergic factor; the failure to reckon with this factor is the chief cause for postoperative recurrence.

ABSTRACT OF DISCUSSION

DR. WARREN T. VAUGHAN, Richmond, Va.: Drs. Kern and Schenck conclude that nasal polyps of the mucous type are probably invariably allergic. They emphasize the need for collaboration between the rhinologist and the allergist. There was a time when the rhinologist insisted that all hay fever, vasomotor rhinitis and even asthma belonged in his field. Then the allergist came along and insisted that they were his. Now, not infrequently, each one wishes that it belonged to the other. Most of the past statistics are worthless. In a review of the literature from both fields as to the incidence of nasal disorder or sinus disease in chronic perennial asthma the figures run from 14 to 90 per cent. There is no room for any sort of conclusions here, because there is too much variation. The results of treatment from the rhinologic point of view vary with different authors from zero to a hundred per cent. The trouble is that they have taken every case of asthma and considered it as a single disease. There are many, many forms of asthma, depending on the cause. With allergic therapy one finds it almost as bad, anywhere from 24 to 90 per cent. The reason why it has not been possible to correlate these past observations is that physicians have not distinguished between extrinsic allergy due to factors reaching the subject from without, and intrinsic allergy. Obviously one will not expect to get the same type of result when the cause is due to some intrinsic factor: focal infection, sinus infection, or some other unrecognized factor in the patient himself; and one will find that the results from allergic therapy are far better (68 per cent), in the extrinsic than in the intrinsic cases (27 per cent relief by allergic methods). The latter is the group in which best results are to be obtained by collaboration between the rhinologist and the allergist. Ten years ago the internist who was interested in allergy was considered by his friends a hyperenthusiast. Now, all interested in internal medicine know there is such a thing as allergy. The rhinologists are in about the stage the internists were in ten years ago. There are a few rhinologists who are getting hyperenthusiastic on allergy, but the rhinologist will be in the best possible position to study allergy, preferably in collaboration with an allergist, as soon as he realizes that probably 50 per cent of his patients have some form of allergy that should be recognized and treated.

DR. JONATHAN FORMAN, Columbus, Ohio: Polypi, as they come into the pathologic laboratory, have been, in the past, neglected. The paper of Drs. Kern and Schenck offers a valuable classification that should be in the hands of all pathologists doing tissue work for nose and throat men. With this contribution as a keystone to the arch built by other workers, I feel that it can now be said that the presence of a nasal polypus means the existence in that nose of an allergic state. It must be remembered, however, that by allergy is meant only an altered, unusual reaction. Therefore there must be many different types of allergy. I am saying this so that many men may escape the pitfall of thinking that they can get results by doing a few skin tests. The tests are valuable, I am not decrying them; but they must be used in conjunction with other methods, and they must be used, above all, with brains. There are at least four types of allergic coryza that may form the background for the development of polypi. There is an atopic form characterized by a positive family history, by a personal history of other allergic manifestations, by the presence of the eosinophilia, and, finally, by positive skin tests and passive transfers to normal individuals of the sensitizing antibodies in the serum of the patient. Then there are bacterial allergies, recognized, first, by the elimination of the atopic state, and, secondly, by the history of infection or the demonstration of foci and, finally, by the delayed intracutaneous tests much like the tuberculin reaction to the proper cultures. It is also possible, of course, to have an atopic coryza due to bacterial protein, because bacterial protein is no different from any other protein in its antigenic properties. Then there is what I have dared to call contact allergic coryza, which is recognized by the elimination of both the other types, by the history of exposure and the identification of an offending substance, usually not organic, among the inhalants and contactants of a nose, and by the relief on the avoidance of the offending substance. Finally, there is that group of coryzas which has

been described admirably by Dr. Duke of Kansas City, due to physical agents. If all these things are kept in mind, physicians will begin to look into cases of nasal polypi with a systematic method. They will not be sent to a laboratory and have twenty, thirty, sixty, 200 or 300 skin tests, but they will be studied in a systematic manner. The allergic method must be used carefully and with a well planned program. If one just makes a skin test, one will fall into the error of dermatologists of using intradermal and scratch tests when one should have used contact tests, and using patch tests when one should have used intradermal and contact tests. So here one must use all these methods if one is going to study these patients from the allergic point of view and get the results that one should get. The removal of the polypi without taking care of the allergic background is the explanation of the recurrences that are so frequent.

DR. HARRY L. BAUM, Denver: For many years I have been convinced that most of the edematoses in the nose and in the accessory sinuses are allergic. I have never had the temerity to state definitely that all are and that allergy is the sole cause of nasal and sinus edematoses or mucous polyps. Drs. Kern and Schenck would freely admit that it is not possible to prove conclusively the contention of their paper. They do not claim positive proof, and when it is realized that there is no method of proving definitely that any condition is allergic it would be equally impossible to prove that this particular condition is always allergic. The assumption of allergy must always be based on the results attained when cases are studied according to certain criteria. These criteria are: Does the patient have a personal or family history of allergy? Do his mucous membranes have the clinical appearance of allergy? Does he respond positively to certain skin tests? Are eosinophils present in unusual numbers in his secretions, in his tissues, and possibly in his blood? And, finally, do we have the presumptive evidence of apparent cure by means of the methods of treatment commonly used by allergists? In most instances, some or all of these criteria can be brought to bear with positive results in cases of nasal mucous polypi. Therefore, rhinologists must be willing to accept the tentative conclusion that nasal mucous polypi, in the great majority of instances, are allergic. The paper implies that more nasal diseases are allergic than rhinologists have believed in the past. It has been thought that nasal polypi were indications of sinus disease, and it has been accepted as axiomatic that this was true; but physicians have not gone on to define the nature of this sinus disease. After all, the nasal polyp is nothing more than an extruded portion of the edematous lining membrane of a cavity. Therefore there may be no more disease in that cavity than the edema which results from allergy, and certainly there would be no indication in such a case for surgery within the cavity, because by the removal of the allergic mucous membrane one does not cure the underlying condition, which is systemic and not local. By proper consideration of that one point, medical practitioners may be led to greater conservatism in sinus surgery. Every rhinologist should be, to at least a certain extent, an allergist and should either himself be conversant with the common practices in the study of allergy or should be in close cooperation with one who is; and I am led also to many other implications in regard to sinus diagnosis based on the presence of polypi or edematoses in the nose and sinuses.

DR. H. P. SCHENCK, Philadelphia: Two of the discussers quoted Dr. Kern and me as saying that 100 per cent of nasal polyps are due to allergy. We do not state that all nasal polyps are due to allergy but that all mucous nasal polyps are due to allergy. Photomicrographs showing the typical structure of mucous polyps make their characteristic design evident. In contrast is a photomicrograph showing a neurogenic tumor, possibly a schwannoma (a type of neurofibromatosis), supposedly due to proliferation of cells in the sheath of Schwann. The patient had had nine operations in ten years for the removal of nasal polyps. At the tenth operation, six polyps, amounting to about 20 cc., were removed. Grossly they resembled mucous polyps but microscopic section disproves the clinical diagnosis. The crux of the situation rests on careful pathologic examination of every supposed polyp removed.

Clinical Notes, Suggestions and New Instruments

A STRABISMOMETER

J. L. BRESSLER, M.D., CHICAGO

Early in September 1933 an orthoptic clinic for the treatment of squint was started at the Illinois Eye and Ear Infirmary. From the beginning, the greatest difficulty with which we were confronted was the getting of accurate measurements of the angle of deviation.

The development of the instrument described here occurred following a suggestion made by Dr. Leo L. Mayer, a member of our staff. In our opinion this instrument has many distinct advantages over the perimeters previously used for this pur-

Strabismometer developed in the orthoptic clinic at the Illinois Eye and Ear Infirmary.

pose. We first used the ordinary table model perimeter and later Schweigger's hand perimeter. Both of these instruments have obvious faults, which interfered with an accurate determination of the angle.

Our new instrument has eliminated many of these objectionable features. Its advantages are as follows:

1. The instrument slides up and down in a tubular weighted stand. It can be firmly fixed at any desired height to accommodate varying heights of patients.

2. It cannot sway from side to side or up and down. Once centered and fixed, it remains so. The eyepiece, which is 13 inches from the center of the arc, is marked so that accurate centration is neither difficult nor a matter of guesswork.

3. The horizontal arc consists of a steel bar about five-eighths inch in height, over which the patient can readily fix

Read before the Section on Ophthalmology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

the distant light and over which the examiner can easily see the reflex of his ophthalmoscope light on the patient's cornea.

4. This arc is marked with graduations in single degrees. All other perimeters have markings only every 10 degrees. Our instrument makes readings more accurate and eliminates guessing.

5. For the near fixation point we have a movable target which slides along the upper edge of the arc and can be placed in position when needed.

This instrument was built for us by Mr. Freeman of the American Optical Company of Chicago.

A CASE OF GRANULOPENIA FOLLOWING AMIDOPYRINE, WITH TWO RECURRENCES

WINGATE M. JOHNSON, M.D., WINSTON-SALEM, N. C.

Mrs. B. N. J., aged 41, the wife of a physician, had a left supra-orbital neuralgia for which she took amidopyrine in 5 grain (0.3 Gm.) doses from one to four times a day for about two weeks. On May 6 she began to ache and had a temperature of 100 to 101 F. The next day her gums became moderately inflamed. May 8 she was chilly, the aching became worse, and she began to feel prostrated. The prostration became more marked, the temperature elevation continued, and the gums became swollen and spongy. On May 10 a leukocyte count was 1,400, with no granulocytes. She was taken to the North Carolina Baptist Hospital and given 8 minims (0.5 cc.) of turpentine into the deltoid muscle of the left arm, as suggested by Roberts and Kracke.¹ In addition she was given 10 cc. of pentnucleotide, in the buttocks, twice a day for eight doses. There was a sharp febrile reaction and a very unpleasant feeling of numbness after the first two doses of pentnucleotide, becoming less marked with successive doses. Considerable swelling and pain developed in the region where the turpentine was injected, but this subsided without suppuration.

Daily blood counts were made. From May 10 to 16 the leukocytes remained between 1,400 and 1,550. On May 17 the count was 1,650; May 18, 1,900, with an occasional immature granulocyte. After that successive daily counts were 2,300, 3,600, 4,950 and 6,600 on May 22, with 63 per cent granulocytes. The red blood cells remained throughout between four and a half and five million, with a hemoglobin of 70 per cent.

At this point the patient was allowed to go home. The blood picture was normal, June 2, and a count was not made again until June 11, just at the end of menstruation (she had menstruated the first week in May). She was then feeling so much worse that a blood count was made, and her leukocytes were found to be only 2,100, with 10 per cent granulocytes. She was given daily injections of liver extract, 3 cc. each, for five doses. The leukocytes gradually rose by June 19 to 6,550, with 53 per cent granulocytes.

Her next menstruation began June 29, lasting six days. On July 2 her leukocytes were 4,100, with 50 per cent granulocytes. They rose to 6,450 on July 12, with 64 per cent granulocytes.

Throughout her last two menstruations, the blood picture has remained normal, from 6,150 to 7,000 leukocytes, with 65 to 67 per cent granulocytes.

During the first two menstrual periods after her return from the hospital, the patient took one or two tablets of cibalgine daily for the first two days; during her last period she did not take anything. Each cibalgine tablet contains $3\frac{1}{2}$ grains (0.2 Gm.) of amidopyrine, combined with the hypnotic dial.

While this case may illustrate the deleterious influence of menstruation on granulopenia, as suggested by Thompson,² I am reporting it as one more link in the chain of evidence against amidopyrine. The two recurrences when the drug was taken, and the absolute lack of disturbance during the last two menses when it was not taken, certainly suggest that amidopyrine played the villain's rôle in this case.

ARTIFICIAL PNEUMOTHORAX

CLINICAL LECTURE AT CLEVELAND SESSION

J. ARTHUR MYERS, M.D.

MINNEAPOLIS

Itard coined the term "pneumothorax" in 1803 to designate the existence of air in the pleural cavity. He had observed three cases of spontaneous pneumothorax and made reference to the cases described by Selle and Boyle. Since that time large numbers of cases of spontaneous pneumothorax have been reported, particularly since the advent of the x-rays, and numerous references have been cited in the literature. Thus nature demonstrated that a lung may be partially or completely collapsed while the opposite lung carries on adequately the respiratory functions of the body. Moreover, observation revealed the fact that marked improvement of pulmonary disease sometimes occurs following spontaneous pneumothorax. These facts brought to light great possibilities in both the diagnosis and treatment of chest diseases.

After carrying out several experiments on animals, Carson, a Scotch physician practicing in Liverpool, in 1822 concluded that one lung can be collapsed artificially with safety by introducing air into the pleural space. Although he recommended that artificial pneumothorax be used in the treatment of pulmonary tuberculosis in man, he apparently did not administer it. Only a decade later, McRuer of Bangor, Maine, made some independent observations, which also led him to recommend immobilization of the diseased lung by introduction of air into the pleural cavity. In 1882 Forlanini of Italy also suggested artificial pneumothorax in the treatment of pulmonary tuberculosis.

Although there is reference in the literature to the introduction of air into the chest for the treatment of disease by the Greek physicians in the fourth century B. C., the modern practice of artificial pneumothorax dates back to 1888, when Forlanini introduced air into the pleural cavity of a patient suffering from pleural effusion, and in 1892, when he actually collapsed a diseased lung.

Apparently not knowing of the work of Forlanini and from independent observations and thinking, Murphy of Chicago reported some actual cases he had treated by artificial pneumothorax in 1898. Tice began to use artificial pneumothorax about the same time as Murphy, and Lempke continued the work that Murphy began. Since that time artificial pneumothorax has become a standard method of treatment. Waring speaks of it as a "procedure that has unquestionably saved hundreds of thousands of lives, and as long as mankind suffers from tuberculosis will remain a most valuable method of treatment."

METHOD OF ADMINISTRATION

In collapsing the lung by this method, pure nitrogen, pure oxygen, carbon dioxide and sterile air have been used. Although these gases in pure form may have

Prepared with the aid of a grant from the Medical Research Fund of the University of Minnesota Medical School.

From the Departments of Internal Medicine and Preventive Medicine, University of Minnesota Medical School, and the Lymanhurst School for Tuberculous Children.

certain minor advantages, filtered air has been found to be the most practical and satisfactory.

Simple and inexpensive devices can be made or may be purchased for the administration of air into the pleural cavity. These are equipped with manometers that determine when the point of the needle is in the pleural cavity. When one is certain of this fact, a small amount of air, approximately 25 cc., is allowed to flow into the pleural cavity. If the manometer shows that the pressure is still definitely negative, another 50 cc. of air may be introduced. If the manometer readings are still good, one should continue to introduce small amounts, watching the manometer readings until approximately 200 to 250 cc. has been introduced. This amount suffices for the initial treatment in the case of an adult and should be decreased for children, according to the size of the chest. The second treatment should be administered in approximately forty-eight hours, and here again, with the same meticulous care, one should introduce only small amounts of air between manometer readings until approximately 300 cc. has been introduced, provided the pressure remains negative. The third treatment is administered about seventy-two hours after the second; the fourth about five days after the third. The subsequent treatments may be administered at weekly intervals. Later, many patients may have their intervals increased to ten days or two weeks. However, this must be determined by the rapidity with which the air is absorbed from the pleural cavity and by the degree of collapse one desires to maintain. When no adhesions are present, the lung collapses to the desired degree without the use of positive pressure. When adhesions are present, one is justified in using slight positive pressure after the patient has been on treatment for some time.

Some workers later use high positive pressures in order to stretch the adhesions sufficiently to permit a satisfactory collapse. Others prefer never to use more than a slightly positive pressure because of the possibility of tearing adhesions.

COMPLICATIONS

The passing of a needle through the chest wall for the purpose of introducing air into the pleural cavity is attended by some dangers, which must be recognized by every physician administering this form of treatment. The first is that of gas embolus, which may result if the tip of the needle is in a pulmonary vessel when air is introduced. This accident may be avoided by refraining from the administration of air until the manometer readings indicate with certainty that the point of the needle is in the pleural cavity. Probably a far more common cause of gas embolus is the giving way of an adhesion at its pulmonary attachment, resulting in the tearing of pulmonary vessels in which there is negative pressure. Thus, air that has been introduced into the pleural cavity is readily sucked into these vessels and may be transmitted to the coronary or cerebral arteries. This is a most distressing complication and sometimes is fatal. Fortunately, it occurs rarely. In the administration of approximately 20,000 treatments during the past fourteen years I have seen five cases of gas embolism, only one of which was fatal. The last one occurred six years ago.

Another complication is spontaneous accidental pneumothorax. This may be due to injury by the needle of the visceral pleura and pulmonary tissue immediately

subjaacent, thus allowing air from the lung to leak into the pleural cavity. The more common cause of this complication is the giving way of an adhesion at its attachment to the visceral pleura, thus producing a fistula through which air passes from the lung to the pleural cavity. Again, spontaneous collapse of the contralateral lung is occasionally seen. Such accidents may occur at any time during the administration of treatment or during the interval between treatments. When the lung spontaneously collapses suddenly and a flap of visceral pleura serves as a valve to prevent the return of air from the pleural cavity to the bronchial tree, relief must be provided by removal of air in a short time to prevent death. I have seen only two patients who I believe died from spontaneous or accidental pneumothorax. In both, death occurred within a few minutes after the onset of symptoms and before a physician could reach them. Although there was no postmortem examination and other physicians are inclined to believe that each patient died of cardiac failure, I am still of the opinion from the symptoms described by members of their families and other associates that death was due to spontaneous pneumothorax.

Another complication is fluid in the pleural cavity. Small serous effusion is seen very frequently in artificial pneumothorax patients. It probably would be found in every case if one searched diligently and persistently enough for it. The serous fluid that lubricates the pleural layers gravitates to the most dependent part of the pleural cavity when air is introduced. Such effusion is of no significance. Large serous effusion occurs less frequently. It is often accompanied by symptoms that closely simulate those of influenza but usually persist longer. After the symptoms subside, the patient regains strength and a sense of well being in a short time. If not aspirated, the fluid may remain for weeks or months and apparently favors the formation of obliterative adhesions, which may make further treatment impossible. Fibrin bodies in the fluid are observed in some cases and cast dense shadows on the x-ray film.

Some large effusions that appear to be only serous in the beginning are later found to be infected with tubercle bacilli or other pyogenic micro-organisms, or both. Thus, empyema becomes a complication that is most serious when it is due to mixed infection. Empyema rarely if ever results from micro-organisms reaching the pleural cavity through the needle. The cause of tuberculous empyema is obvious. Mixed infections usually result from pleural fistulas, which allow pyogenic micro-organisms to pass from the lung into the pleural cavity.

When instituting artificial pneumothorax, one must keep under close observation the mediastinum, since in some persons it is very flexible. This may result in considerable respiratory and cardiac embarrassment. In some cases mediastinal hernia is seen. When the mediastinum is too flexible to allow satisfactory collapse of the diseased lung, there are methods of stabilizing it, such as the introduction of oil into the pleural cavity.

Occasionally febrile reactions result from artificial pneumothorax treatment. They are probably due, for the most part, to increased absorption of toxins as a result of the collapse of the diseased area. These usually are not serious and disappear in a short time.

During and immediately following the first treatment, the patient may experience a sensation in the chest that

is difficult to describe but is often spoken of as "heaviness." This is not significant and usually lasts only a few minutes to an hour or so. During the first twenty-four hours after the first treatment there may be discomfort in the chest, which varies in intensity from a slight ache to excruciating pain. This is caused in most cases by adhesions. The pain may be controlled by codeine. Usually it is not present following subsequent treatments.

In some cases, when artificial pneumothorax is attempted, pleural adhesions are encountered. They may vary in size and extent from those which completely obliterate the pleural space to those which are only thin strands and stretch to such an extent that satisfactory collapse is obtained. Between these extremes are seen adhesions, which become definitely stretched but not enough to permit the closing of cavities or adequate collapse of the diseased area to allow a good clinical result. In many such cases, intrapleural pneumolysis is practiced with great success. The adhesions are cauterized near their attachment to the parietal pleura, following which the lung often collapses in a satisfactory manner as artificial pneumothorax is continued.

In an occasional case, during the first few hours of treatment, air leaks through the needle tract and causes subcutaneous emphysema. This is of no significance but may cause the patient some discomfort and considerable alarm. After the first treatment is administered, the physician should take time to discuss the various possibilities with regard to pain, subcutaneous emphysema, and so on. If this is not done, the patient's confidence may be lost if some of these possibilities actually occur.

EFFECT ON NORMAL AND DISEASED LUNG TISSUE

Since artificial pneumothorax was first instituted, much has been learned about its effect on normal as well as on diseased lung tissue. Through observations it has come to be looked on as a simple procedure rather than a drastic one, as it was at first thought to be. Careful observations have revealed the fact that no serious harm comes to normal lung which is kept under a state of collapse over a long period of time. Gardner has shown that alterations resulting from collapse of the lung consist of the development of fibrous tissue in the pleura and connective tissue coats of the blood vessels and bronchi. The degree of permanent changes caused by artificial pneumothorax in fifteen cases studied pathologically was found to depend on the extent and degree of injury by the tuberculous process. There are slight changes in the circulatory system when artificial pneumothorax is instituted, but they are harmless. The slight deviations from normal sometimes observed in the electrocardiogram are due to pleural and mediastinal adhesions that have altered the position of the heart rather than to myocardial factors. Basal metabolism is not altered in a significant way. Therefore, artificial pneumothorax can no longer be looked on as a drastic procedure when indicated in the treatment of pulmonary disease. Of the various forms of collapse therapy, artificial pneumothorax is the simplest and yet the most effective.

Fortunately, diseased areas in the lungs, except consolidations, dense fibrosis and the like, collapse more readily than normal areas, owing to the fact that in such areas there is little or no diminution of contractility

but marked impairment of expansibility. Thus, selective collapse actually occurs. This makes it possible in many cases to keep the diseased area well collapsed while a considerable part of the normal lung tissue is functioning.

ARTIFICIAL PNEUMOTHORAX IN DIAGNOSIS

Since artificial pneumothorax is a simple procedure and when carefully performed does no harm, it has been found to be a very valuable diagnostic procedure, especially in diseases of the mediastinum, pleura, lungs, ribs and chest wall when obscure conditions exist. It has been used to determine definitely whether interlobar empyema exists and whether true cavity formation is present in the lung, as well as in mapping out other pulmonary conditions.

ARTIFICIAL PNEUMOTHORAX IN TREATMENT

Pulmonary Tuberculosis—Formerly the indications for artificial pneumothorax were hemorrhage, cavity formation, or extensive disease involving one lung. In recent years the indications have been extended. Not long ago a small area of disease in the opposite lung was looked on as a contraindication to artificial pneumothorax. However, paradoxical as it may seem, disease in the opposite lung often improves following the institution of artificial pneumothorax on the side of the more extensive disease. Such improvement is probably due to several factors. First, by reducing the toxemia the patient's general condition is definitely improved, giving the body a better chance to control the lesion in the contralateral lung. Second, the sputum is soon rendered negative or entirely disappears, so that the feeding of the opposite lung and other parts of the respiratory tract with tubercle bacilli is discontinued. Third, the effect of pneumothorax is not confined to the lung being treated but has a slight immobilizing effect on the opposite lung. In case the disease in the opposite lung does not come under control or in case a new lesion appears in it, partial bilateral artificial pneumothorax may be instituted with a good deal of success. The reserve lung capacity is so great that it is possible to collapse each lung to about one-half its volume without causing dyspnea or other discomfort to the patient. A good many workers now look on minimal, progressive pulmonary tuberculosis of the reinfection type as a definite indication for artificial pneumothorax. Conditions that were formerly thought to be a contraindication, such as tuberculous laryngitis and enteritis, are no longer considered so, as they may improve if the pulmonary lesion is brought under control. Even in cases of coexisting pulmonary carcinoma, artificial pneumothorax may render the patient's sputum negative until death results from malignancy. Diabetes is not a contraindication; in fact, many diabetic patients with coexisting pulmonary tuberculosis now have their diabetes treated successfully by modern methods and their pulmonary lesions brought under control by artificial pneumothorax. One of my patients has been under treatment for both conditions since 1925.

The main contraindications for artificial pneumothorax are cardiac disease, asthma, severe grade of emphysema with markedly reduced vital capacity, and extensive bilateral tuberculosis.

Rest has long been looked on as the most important factor in the treatment of a tuberculous lesion in any part of the body. Strict bed rest alone reduces the activities of the lungs very slightly. They continue

breathing at the rate of approximately 25,000 times a day. This probably is one of the reasons why bed rest alone so often fails. With satisfactory collapse by artificial pneumothorax, the diseased organ is actually at rest. This treatment has two main effects on pulmonary tuberculosis. First, the growth of tubercle bacilli is definitely inhibited. Second, venous stasis and some blocking of the lymph circulation occur, which are believed to stimulate the growth of connective tissue and aid in healing. Thus, it is well known that the two factors so significant in the control of tuberculosis are present; namely, the inhibition of proliferation of tubercle bacilli and the stimulation of fibrosis. Relief from symptoms, such as cough and expectoration, fever, increased pulse rate and impaired digestion, is very quickly experienced in many cases.

When cavities are present and their walls are not too thick, artificial pneumothorax closes them by bringing the walls in apposition where they become adherent and are permanently obliterated. Thus, artificial pneumothorax is a simple, harmless procedure and yet most effective in the treatment of pulmonary tuberculosis.

Unfortunately, most of the results of artificial pneumothorax treatment observed to date deal with cases that were moderately or far advanced when the treatment was begun. The first object of artificial pneumothorax treatment is to render the sputum negative or to prevent a case with negative or no sputum from becoming positive, thus protecting the patient as much as possible against endogenous reinfection and protecting his associates and the community against contamination with tubercle bacilli. By the time the disease has become moderately or far advanced most patients have positive sputum, whereas in the minimal stage this is true of only approximately one third.

The Committee on Treatment of the American Sanatorium Association, consisting of Douglass, Peters and others, found that at the termination of artificial pneumothorax as recommended by the physician 66.1 per cent had negative sputum, whereas among those whose lungs reexpanded before their physicians recommended it only 46.9 per cent had negative sputum. A much higher percentage would have had negative sputum if the treatment could have been instituted while the disease was in the minimal stage. They classified 405 patients with reference to sputum at the termination of treatment according to the condition of the treated lung before collapse. Approximately 11 per cent more were negative when slight or no cavitation was present before treatment was begun than among those who had definite cavity formation. Thus, the less disease and destruction done before the lung is collapsed, the better the chances of rendering the sputum negative to tubercle bacilli.

In most groups of cases reported, those in which collapse was possible have shown a 20 per cent or more better chance of becoming well or able to work than those who were not treated by this method. Thus, the treatment is very much worth while even in moderately or far advanced cases, yet many such cases require long periods of bed rest in addition to artificial pneumothorax treatment.

Although the treatment of moderately and far advanced cases by pneumothorax has been found to be far superior to previous forms of treatment, such as strict bed rest, still it was not entirely satisfactory because the patients had often lost their best chances

of recovery before the treatment was begun. Therefore the results obtained leave much to be desired. Moreover, when cavities have been formed, a high percentage of patients were disseminating tubercle bacilli to their associates.
